INTERNATIONAL REVIEW  
OF THE SCIENCE  
AND PRACTICE OF AGRICULTURE

MONTHLY BULLETIN  
OF AGRICULTURAL INTELLIGENCE AND PLANT DISEASES

INDEX 1918

ROME  
~~PRINTING OFFICE OF THE INSTITUTE~~  
1918

# CONTENTS

PREFACE . . . . .	Page	7
I. — Index of Original Articles . . . . .	»	9
II. — Index of Agricultural Intelligence :		
A) Subjects . . . . .	»	10
B) Authors . . . . .	»	72
III. — Index of Plant Diseases :		
A) Subjects . . . . .	»	84
B) Authors . . . . .	»	124
IV. — Errata . . . . .	»	160
V. — Weights, measures and money of the various countries with their English equivalents . . .	»	161
VI. — Periodical Publications Reviewed. . . . .	»	165

312044

IARI

## P R E F A C E

---

This index though arranged alphabetically retains the grouping of the subjects used in the *International Review*.

Except in the case of the original articles, which are numbered according to their pages, the numbers of each subject refer to the paragraphs in the *International Review*.

The index consists of three parts: one of the original articles, one concerned with Agricultural Intelligence and the last with Plant Diseases.

In case of errors in the Bulletin with reference to scientific terms and the names of authors, it should be noted that the correct spelling can be relied upon in the Index (See Errata).

The Table used for the conversion of the Weights, Measures and Money values of the various countries to the Metric System is included. A list is also given of the Periodical Publications reviewed by the Bureau.

This Index was prepared by redacteurs : Dr. Giulio Provenzal and Prof. Giulio Trinchieri, the latter compiled the Index of Plant Diseases. The whole was adapted to the English Edition by rédactrice Miss M. L. Yeo.

## I. — INDEX OF ORIGINAL ARTICLES

- AROSNIUS. E. - The Forest Industry in Sweden. *page* 1,  
ROBERTSON, W. A. N. — The Live Stock Industry in Australia, *page* 529.  
TARCHETTI. A. - Mechanical Ploughing, *pages* 905, 1017, 1129.

## II. — AGRICULTURAL INTELLIGENCE

### A) INDEX OF SUBJECTS

- ABROMA AUGUSTA*, 1357.  
*Abutilon Theophrasti*, 628.  
Ahyssinia: Coffee, Wild and Cultivated Species and Varieties, 763.  
*Acacia*: *A. Aroma*, 772. *A. decurrens*, 1325, *A. Farnesiana*, 994. *A. horrida*, 628.  
*Acanthosyris spinescens*, 772.  
*Acartomyia mariae*, 1260.  
*Accipiter* sp., see Ectoparasites, 880.  
Acetic Acid: Manufacture on Rubber Estates, 1414.  
*Achillea lanulosa* ('Yarrow'), 166.  
*Achradelpha viridis*, 138.  
*Achama rosaeifolia* (Makamako shrub), 44.  
Acorns: As Food for Cattle, 66. Utilisation by Alcoholic Fermentation, 95. Acorns as Food for Poultry, 1262.  
Acremeter, 560.  
*Acrocomia* s.p., 5.  
*Adansonia digitata* ("Baobab"), 1075.  
Adenine, 546.  
*Adonis microcarpus*, 994.  
Adulteration and Fraud: Impossibility of Watering Milk by giving Large Quantities of Water to the Cow, 63. Methods for determining Adulteration of Wines, 93.  
*Aeschynomene aspera*, 1075, *A. spinulosa*, 1357.  
*Aesculus assamicus*, 628.  
Africa, French West: Rearing the Manatee as Food Animal, 1393.  
Africa: Tobacco in Nigeria, 5. Lime Fruit in Nigeria, 254.  
*Ajzelia palembanica*, 832.  
*Agastiche urticifolia* ("Horsemint"), 166.  
Agave: Cultivation in Tropical and Intertropical Countries, especially Madagascar, 1359 and *see* Fibres.  
Agen Plums and Prunes, 818.

*Agoseris glauca*, Mountain Dandelion, 166.

Agricultural Botany, *see* Chemistry and Plant Physiology.

Agricultural Institutions: Agricultural Education in the United States, 127. First year Course in Home Economics for Southern Agricultural Schools in United States, 723. Foundation of a High School of Agriculture and Forestry in Indo-China, 1199. Organisation of Public Professional Teaching of Agriculture, in France, 1323. Tractor School in Illinois, U. S. A., 1395.

Agricultural Legislation: International Yearbook 7th year (1916), 1. Awards for the Location of Workable Phosphatic Deposits, in Germany, 18. Results of Enquiry of the Office of Agricultural Information of the French Ministry of Agriculture on Manitoba Wheat, 34. Work of the Philippine Bureau of Forestry, 53. Agricultural Education in U. S. A., 127. Official Measures adopted in the Argentine for the Control of the Tick Transmitting "Tristeza", 776. Facilities accorded to Official Agronomists for the Purchase of Automobiles, in Canada, 950. Encouragement in growing of Castor-oil Plant in Indo-China, 1188. Work done by the Administration to encourage development of Silkworm Rearing, in Indo-China, 1264. Measures taken in Hungary for the Production of Sugar Beet Seed, 1348.

*Agropyron flexuosum*, 166. *A. scabrum*, 417. *A. spicatum*, 166. *A. violaceum*, 166.

*Agrostis Rossae*, 166.

*Ailanthus*: *Ailanthus glandulosa* as a Paper-Yielding Plant, 170.

Ajowan, *Carum copiticum*, 1075.

*Anaga Iva*, 994.

*Albizzia Lebbeck*, 5.

"Alcaparra". *Cassia vernicosa*, 1258.

Alcohol: Importation and Exportation of Products and Bye-products of Dry Distillation of Wood in Sweden, *page*, 7. Use of Horse Chestnuts for the Production of Alcohol, 94. Utilisation of Acorns by Alcoholic Fermentation, 95. Industrial Alcohol in South Africa, 209. Production of War Alcohol with Perry Pears, 215. Production of Alcohol from Algae, 569.

*Aleurites*, spp., 53.

Alfalfa, *see* Lucerne.

Algarroba. *Prosopis Siliquastrum*, 1248.

Algae: Use of certain Marine Algae for feeding Horses, 320. Production of Alcohol from Algae, 569. Investigations into Composition of Seaweeds with a view to their Utilisation as Cattle Food in Netherlands, 1137.

Algeria: Cultivation of Castor-oil Plant, 526. Cotton, 865. Selection of Barley, 973. Manitoba Wheat, 1230.

Aliso (*Eupatorium* sp.), 772.

*Allium fibrillum*, *A. platyphyllum*, *A. validum*, 166.

*Alloteropsis Ekcloniana*, 628.

Aluminium: As a Factor Influencing the Effect of Acid Soils on Different Crops, 390. Toxic Action of soluble Aluminium Salts upon the growth of the Rice Plant, 518.

*Amorphophallus* spp., 1191.

*Amphipogon strictus*, 417.

*Amygdalus* spp., 1086.

*Amyris balsamifera*, 5.

*Anacardium excelsum*, 138.

*Anacolosa luzoniensis*, 'Cjalo', 138.

Analysis of Agricultural Products:

Recent Investigations and Observations made at the Imperial Institute, London, 5. Production of Wheat and other Cereals in Egypt, 5. Flax growing in Egypt, 5. Cot-

- ton growing in Australia, 5. New Paper Making Materials, 5. Some New Oil seeds from American Palms, 5. Nuts of *Ricinodendron Rauteneii* S. W. Africa, 5. Production of Sandalwood oil in Mysore, 5. Tobacco from Northern Provinces, Nigeria, 5. Fertilising Value of some Household Wastes, 15. Methods for Approximating the relative Toxicity of Cottonseed Products, 64. Food Value of Waste Leaves of Different Varieties of Cabbage, 65. Value of Cider Apples, Perry Pears and their Respective Pomace as Food for Farm Stock, 68. Vegetation on Swamps and Marshes as an Indicator of the Quality of Peat soil for Cultivation, 132. Value of Coconut Poonac as Manure, 136. Oil yielding Plant—" Ngart ", 136. Composition of Grain Sorghum Kernels, 140. Analysis of Argentine *Bragrostis* Hays, 165. Composition of Hay cut at different Dates, 184. Contribution to the Study of Alcoholic Ferments, 213, 214. Photographic Analysis of Dried or Fresh Eggs, 223. Analysis of fruits of *Citrus Medica* var. *acida* in Nigeria, 254. Composition of Pistachio Nuts and Oil, 254. Average Composition of Treated and Untreated Garbage, 265. Composition of Three Padder Pulses in India, 295. Composition of certain Marine Algae for Feeding Horses, 320. Analysis of Zauia Palm Nuts and Leaves, 401. Composition of Potato Plant at Various Stages of Development, 415. Chemical Study of Nuts of "Sanga-sanga", *Ricinodendron africanum*, 421. Analysis of Catalase Activity of American Wheat Flours, 464. Composition of Brazilian Palm Oils, 465. Detection of Lime used as a Neutralizer in Dairy Products, 470. Chemical Composition of Lime Sulphur Animal Dips, 541. Composition of Milk, 577. 578. Composition and Market Qualities of Butter when Corn Silage is fed with Cottonseed Meal, 696. Determination of Fat in Certain Milk Products, 697. Changes in the Nitrogen Content of Stored Soils, 733. Fats and Fatty Acids of Grain Sorghums, 744. Substitute for Litmus for Use in Milk Cultures, 908. Certain Changes in some of the Nitrogenous Constituents of Milk caused by Bacteria, 909. Moisture Content and Solubility of Cow Manure, 910. Analysis of 129 varieties of Cheese, 914. Researches on the Physical and Chemical Constants of the Oily Matter of Egg, 917. Composition of *Elaeis Poissonnii*, 986. Oil Content, Keeping Qualities and Commercial Possibilities of Para Rubber Seed, 987. Analysis of "Cocoa Tea", 992. New Method for Determining the Watering of Wine 1033. Deterioration of Condensed Milk: Estimation of its Acidity, 1046. Bacterial Precipitins and the Detection of *Bact. botulinus* in Preserved Foods by the Thermo-Precipitation Method, 1047. Rice and the Chemistry of Food, 1072. Composition of Essential Oils of Cyprus and their Cakes, 1075. Chemical Composition of Loganberry, 1124. Contribution to the Chemical Composition of Pineapple and the Materials necessary to Cultivation, 1125. Prussic Acid Content in the "Pegya" Bean (*Phaseolus lunatus* var.), 1227. Properties and Botanical Origin of "Cu-nâu", 1236. Analysis of Portuguese Colares Wines, 1278. Study of the Viscosity of Various Colonial Oils, 1279. Oil

- of *Jessenia polycarpa* Nuts, and *Caryodendron orinocense* Seeds in Colombia, 1280. Note on Orange Pip Oil, 1281. On the Composition of Fruit Juices, 1282. Composition of Flax Stalks from Rhodesia, 1325. Analysis of fruit of *Attalea excelsa*, 1325. Analysis of Samples of Sisal Hemp, 1325. Composition of Samples of Copal from Columbia, 1325. Refractometric Estimation of Milk Sugar, 1417.
- Anatomy and Physiology of Live Stock: Studies on Duration of Life: Temperature Coefficients and Influencing Factors 181. Physiological Effect on Growth and Reproduction of Rations balanced from Restricted Sources, 182. On the so-called Specificity of the Aberhalden Reaction, 183. Animal Calorimetry: The Interrrelation between Diet and Body Condition and Energy Production during Mechanical Work, 314. Chemical Composition of the Placenta of the Cow, 439. Foetal Athyrosis: Study of the Iodine Requirement of the Pregnant Sow, 440. Basal Catabolism of Cattle and other Species, 545. Adeline and Guanine in Cows' Milk, 546. Morphology of Normal Pig's Blood: Effects of Muscular Exercise and Heat of the Sun on Blood and Body Temperature of Normal Pigs, 1008. Investigations into the Action of the Thyroid Gland, U. S. A., 1009. Complementary Studies on the Modification of the Germ Cells of Mammals: Effects of Inhalation of Alcohol Vapour on Guinea-pigs and their Progeny, 1261. Elimination of Arsenic after Ingestion by, and Injection into, Live Stock, and after Absorption through the Skin by Dipping, 1377.
- Andropogon*: *A. affinis*, 417. *A. erianthoides*, 628. *A. intermedius*, 296. *A. muricatus*, 1360. *A. Nardus*, 1360. *A. perflatus*, 417. *A. refractus*, 417. *A. sericeus*, 417. *A. Sorghum*, 296. *Andropogon* pp. 206, 869.
- Animal Dips: Chemical Composition of Lime Sulphur Dips, 541. Dipping in Arsenical Solution, Coal Tar, Creosote or Nicotine, 1259. Bacterium isolated from Cattle Dipping Tank, S. Africa, 1376. Elimination of Arsenic by Dipping, 1377.
- Aniseed, Composition of Oils and Cakes in Cyprus, 1075.
- Anisopogon avenaceus*, 417.
- Anopheles*: *A. maculipennis*, 126. *Anopheles* spp. 1192.
- Anona*: *A. diversifolia*, 628. *A. purpurea*, 628. *A. scleroderma*, 1086.
- Anthisterna*: *A. avenacea*, 296. *A. imberbis*, 417.
- Antilles: Production of Natural Phosphates in Dutch Antilles, 14.
- Apitrefle (Bee Clover), 138.
- Apples: Percentage Composition of Apples and Pomace, 68. Bud Variation in the Duchess Apple, U. S. A., 151. Varieties introduced into U. S. A. 1917. Vars: resistant to Woolly Aphis, 628. Acclimatisation, Selection and Hybridisation in Alaska, 638. Soil Management Investigations in a Young Apple Orchard, 768. Hardy Dwarf Crab Apple introduced into U. S. A. 1916, 1086. Pollination in relation to Commercial Fruit Growing, 1249. Selection in Canada, 1346.
- Arabia: Future of the Yemen Coffee Trade, 1142.
- Arboretum: At Penzance (Saône-et-Loire) France, and Results, 428.
- Arboricola crudigularis*, 880.
- Arboriculture: Nitrates and Nitrication in Relation to Cultural Practices and Plant Growth, 391.

- Results in Italy from sowing Wild-Fig Seed, 532. Direct Influence on the Stock of the Sap, produced by the Scion, and Action on the Plant of Acid Solutions absorbed directly, 630. Investigations into the Autumn Growth of Fruit in Italy, 870.
- Areca Catechu*, 832.
- Arenga saccharifera*, 1325.
- Argentina: *Eragrostis* spp., Value as Fodder Plants, 165. Herd Books of the Argentine Rural Society, 318. Forest Trees, 772. Official Measures Adopted for the Control of the Tick Transmitting "Tristeza", 776. Horse Diseases "Enfermedad de los Rastrojos" in Maize Growing Regions Means of Control, 1254.
- Asses: Properties of the Serum of Animals Hyperimmunised against Glanders and the Choice of Animals for the Preparation of Such Serum Rich in Suitable Antibodies, 56. Census in British India, 317. Argentine Ass Book, 318.
- Aromatic Plants: Essential Oils in Cyprus, 1075. Production in Dutch East Indies, 1360.
- Aristida* sp., 188.
- Aristotelia racemosa*, 44.
- Arrowroot: How obtained in the Philippines, 864. Arrowroot Starch in Tonkin 1191.
- Arsenic: Description of Bacterium which Oxidises Arsenites and another which reduces Arsenates, 1376. Elimination of Arsenic after Ingestion by, and Injection into Livestock, 1377.
- Artemisia Herba-alba*, 994.
- Arundo Phragmites*, 417.
- Ascaris lumbricoides*, 1006.
- Ascension Island: *Enneapogon mollis*, New Wild Grass, 980.
- Asclepias fruticosa*, 5.
- Askaron, 1007.
- Asparagus: Selection in Massachusetts, U. S. A., 285.
- Asphodelus microcarpus*, (*A. pendulinus*), 994.
- Astragalus bisulcatus*, 307. *A. mollissimus*, and *A. diphyssus*, 1283.
- Astrocaryum vulgare*, 5 *Astrocaryum* spp., 465.
- Athagi maurorum*, 994.
- Atriplex Halimus*, *A. mollis*, 994. *Atriplex* spp., 766.
- Attalea*, 5, 1325. *A. jumifera*, 138, 465.
- Aubergine: Investigations into Colour of Fruit in Hybrids, 859.
- Austral Carrot, *Daucus brachiatus*, 417.
- Austral Hollyhock, *Lavatera plebeia*, 417.
- Australia: Cotton Cultivation, 5. Stud Beef Cattle Breeders' Association, 319. Breeders of Purebred Stock in Queensland: Beef and Dairy Cattle, 324. Government Lands, Leased Lands and Alienated Land in Australia, 339. Grasses and Other Fodder Plants of Victoria, 417. Livestock Industry, page 529. Fertilisers in Australia, 510. Salts injurious to vegetation, and their Relationship to Irrigation of Arid and Semi-arid Regions, 728. Interstate Conference of Agricultural Scientists, 1076. Olive growing, 111.
- Austria-Hungry: Wood exports, page 8. International Trade in Fertilisers 14. Measures taken in Hungary for Production of Sugar Beet Seed, 1348.
- Ava, *Piper methysticum*, 138.
- Avocados: *Persea americana*, 138. *P. gratissima*, 628.
- Awnless Brome Grass, *Bromus inermis*, 296.
- Azalea occidentalis*, 1253.
- Azores: Pineapple growing, 995. "Azuki" Bean *Phaseolus angularis*, 1353.

BABASSU, 5.

*Bacillus botulinus*, 953.

*Bacillus mallei*, 56.

Bacteriology and Soil Organisms:

Effect of Different Methods of Inoculation on the Yield and Protein Content of Alfalfa and Sweet Clover, 21. Proof of Microbial Agency in Chemical Transformations of Soil, 259. Decomposition of Soil Protein Substances through the Action of Bacteria, 260. Influence of Fineness of Division of Pulverised Limestone on Crop Yield as well as the Chemical and Bacteriological Factors in Soil Fertility, 263. Influence of Hydrogen-Ion Concentration of Medium on Reproduction of Alfalfa Bacteria, 270. Nitrates and Nitrification in the Soil, 391, 392. Correlation between Bacterial Activity and Lime Requirement of Soils, 505. Protozoa and Phenomena of Reduction in Soil, 731. Influence of Nitrifying Bacteria on Phosphates, 732. Influence of Carbonates of Magnesium and Calcium on Bacteria of Certain Wisconsin Soils, 842. Hydrogen-Oxidising Bacterium from Swamp Rice Soils, 843. Influence of Nitrates on Nitrogen-Assimilating Bacteria, 959. Experiments on the Influence on the Fertilising Power of Sewage of the Bacteria it brings to the Soil, 1207. Studies on the Correlation between the Production of Carbon Dioxide and the Accumulation of Ammonia by Soil Organisms, 1334. Fixation of Nitrogen by Nitrogen-Fixing Bacteria, 1336. On a Water Bacterium living in Bitter Wines that can dehydrate Glycerine, 1408. Micro-organisms and Heat Production in Silage Fermentation, 1422.

*Bacterium arsenoxydans*, 1376.

"Bagilumbang", *Alseodes trisperma*, 53.

*Balanites aegyptiaca*, 994. *B. Maughamii*, 628.

Bambarra Ground Nut, *Voandzeia subterranea*, 1353.

Bamboo: Bamboo Grass, *Glyceria ramigera*, 417. Bamboo Shoots as Vegetables, 1191.

Bananas: In British Guiana, 497. Native Bananas of the Hawaiian Islands, 533. Food Value of Banana, 1198. Action of Ultra-Violet Rays, 1218.

Baobab: *Adansonia digitata*, 1075. "Barbeiro", 1193.

Barley: Cultivated area in Egypt, 5. New Cereals imported into U. S. A., 138. Effect of Greenhouse Temperature on the Growth of Cereals, 142. Selection in Sweden, 113. Cultural Experiments in Sweden, 153. Selection Experiments, N. Sweden, 273. Effects of successive Cropping, U. S. A., 289. Selection in Alaska, 405. Genetic Study on the Awns of a 6-rowed Variety, 408. Identification of Varieties, 523. Sarawak Bean, *Dolichus Hosei*, 628. Selection of Native Barley in Norway, 855. Pure-Line Selection in Quebec, 856. Yields in Illinois, U. S. A., 861. Selection in Algeria, 973. Products in Cyprus, 1075. Relation between Climate and Yield in Sweden, 1327. Aeration and Amount of Growth, 1331. Mutation observed in a Pure Strain of Two-Rowed Barley (*Hordeum distichum*) in Bavaria, 1343. Dietary Qualities of Barley, 1379.

*Bassia* sp., 1075.

Bassoba, 5.

Beans: Dietary Properties of Mixtures of Maize Kernel and Beans, 2. Utilisation of the Civet Bean *Phaseolus lunatus*, Cultivation in Madagascar, 292. Growth of Embryos

- of *Phaseolus lunatus* (Lina Bans), 403. Sarawak Bean (*Dolichus Horsii*), 628. "Mungo peas", Small French Bean at Tonkin 1191. Selection of a type of "Pe-gya" Bean, 1227. Commercial Pulse Crops, 1353.
- Bearded Heads. *Amphipogon strictus*, 417.
- Beechnuts, as Food for Cattle, 66.
- Bee-keeping: The "Sughere" Hive with Cork Frames, 192. Cotton Plant as a Honey-Yielding Plant, 193. Wintering of Bees in Ontario, Canada, 670. Bottini Colantoni, "Subalpina" and "Sughera" Bee Hives, 671. Common Honey Bee as an Agent in Plum Pollination, 640. Artificial Feeding of Bees with Pollen, 1390.
- Beet: Inheritance of Abbreviation of Growth in cultivated Beet, 281. Apparent Mutations of Colour due to Effect of Vicinity, in Sweden, 975.
- Belgian Congo: Parasitic Nematodes, 433. Agricultural Journey, 1310. Fibres from the Belgian Congo, 1325.
- Berberis nepalensis*, 628, *B. spp.*, 114.
- Berberi, *see* Rural Hygiene.
- Berry-Wax, 460.
- Betel, in Sumatra, 832.
- Big Bunch Grass, *Isopyron spicatum*, 166.
- Birds foot Trefoil, *Lotus corniculatus*, 417.
- Bison: Crosses between American Bison, European Bison and Domestic Cow. in S. Russia, 1382.
- Blackberries: Varieties and Cultivation in Indiana, 618.
- Black Brush *Flourensia cernua*, 189.
- Black Hair Grass, *Deschampsia atropurpurea*, 166.
- Black Varnish or Lacquer, 5.
- Blady Grass, *Imperata arundinacea*, 417.
- Blood: Dried Blood as Fertiliser, 173.
- Food Preparations made with Blood and Meat mixed with Yeast, 1169.
- Blow-Fly, 1374.
- Blue Beard Tongue, *Pentstemon procerus*, 166.
- Blue Bunch Grass, *Festuca idahoensis*, 166.
- Blue Erodium *Erodium cygnorum*, 417.
- Borneo: Rubber in North Borneo, 527.
- Boron: Effect of Three Annual Applications on Wheat, 266.
- Botany, Agricultural: Seeds and Plants imported by the Office of Foreign Seed and Plant Introduction 1914, 138, 628, 1086. Studies on Nitrification in Natural Soils and its Importance from an Economical Point of View in Sweden, 624. Identification of grasses by Vegetative Characters, 742. Plant Succession in the S. African Veld, 849. The Glandular Pubescence of Several Species of Medicago: Observations made in California, 850. Plant Ecology and its Relation to Agriculture, 1087. Crop Centres of the U. S. A. from an Ecological Point of View, 1088.
- Bouteloua spp.*, 188.
- Bowstring Hemp, *Sanssevieria spp.*, 1325.
- Brachystevia Randii*, 5.
- Brassica pekimensis*, 628.
- Brazil: Breeds of Pigs, 795.
- Bread-making: War Bread (Unsalted Lime Bread), 5. Milling and Baking Tests of New Wheat (Kantred) in Kansas, U. S. A., 159, 217. On Chalk Bread, 216. Hygienic Disadvantages of using Lime in Bread-making, 253. Milling and Baking Qualities of Australian Wheat, 342. Soluble Nitrogenous Matter as Index of Baking Quality of Flour, 343. Use of Chalk in Bread-making, 344. Food Value of Wholemeal and of 85 % Flour as compar-

- ed with White Flour, 379. Toxic Bread and Flour: Detection and Estimation of Saponins, 380. Characteristics and Quality of Montana Grown Wheat, 463. Catalase Activity of American Wheat Flours, 464. Nutritive Value of White Bread, 616. Digestion of Aleurone Cells Incorporated in 85 % Bread: Experiments made in France, 617. Milling Value of Wheats «Aurore» and «Blé des Alliés», 640, 689. Milling and Bread-Making Tests with Humpback Wheat, in the U. S. A. 642, 690. Determination of Indigestible Residue *in vitro* by Action of Pancreatin on Wheat, or its Milling or Baking Products, 721. Bacterial Deterioration of Bread in Rome, 817. Flours from Rice: and Arrowroot Starch, 1191.
- Breeding of Live Stock: Inheritance of Coat Colour in Swine: Experiments in U. S. A., 69. Observations on Inheritance of Colour and Sex Distribution in certain Animals at the Government Cattle Farm, Hissar, Punjab, India, 885. Crosses between American, European Bisons, and Domestic Cow in S. Russia, 1382.
- Brewing: Sorghum or Dari New Substitute of Malt, used in Brewing 570. Sudan Dura as Brewing Material, 1409.
- Bromus hordeaceus* and *B. marginatus*, 166. *B. inermis* and *B. unioloides*, 296.
- Brown Beetle Grass. *Diplachne fusca*, 417.
- Buckwheat, Two New Vegetable Globulins, 965.
- Buffalo Grass, *Buchloe dactyloides*, 415.
- Building, Farm: Construction of Poultry Houses, U. S. A., 459. Movable Pig Houses, 810. Rapid House Construction with Concrete Studs, 900.
- Bruguiera gymnorrhiza*, 832.
- “Bucheronne”: Machine for Felling and Sawing, 563.
- Bulnesia Gancedu*, 772.
- Bunchgrass-Forage plant, 1365.
- Burro Grass *Scleropogon brevifolius*, 188.
- Butter: Cold storage, 475. Concerning Rancidity, 580. Composition and Market Qualities of Butter when Corn Silage is fed with Cottonseed Meal, 696. Pasteurization of Sour, Farm-skimmed Cream for Butter-making, 819. Studies in Butter Shrinkage, 912. Relation of *Ordium lactis* and *Penicillium* to Keeping Qualities of Butter, 913. Influence of Salt on Changes taking place in Storage Butter, 920. Enzymes of Milk and Butter, 1045. “Renovated” Butter, 1419.
- Butterweed *Senecio triangularis*, 166.
- CABBAGE: Food value of waste leaves of Different Varieties, 65. Hybrid between Kale and Kohl-rabi, 138.
- Cacao: In the New Hebrides, 250. Cacao in Dominican Republic, 530. Analysis of “Cocoa Tea”, a New Substitute used in Great Britain, 992.
- Caesalpinia coriaria* “Divi-divi”, 1363.
- Cajanus indicus* (Pigeon Pea), 1353.
- Cajaput oil, 1360.
- “Calafate” (*Berberis buxifolia*), 1114.
- Calamagrostis canadensis*, *C. Suksdorfi*, 166.
- Calliphora* sp., 1374.
- Callitris quadrivalvis*, 994.
- Calotropis procera*, 994.
- Camellia Oil, 1191.
- Camels: Endoglobular Parasites Causing Disease of Animals in Russian Turkestan, 57. “Jhooling” Disease in British India, 59. Tuberculosis in Egypt, 313. On the Mortality from Trypanosomiasis of Dromedaries, 1368.

- "Camote", *Ipomoea Batatas*, 864.  
*Campomanesia Fenzliana*, 138.  
 Canada: Wood Exports 1906-13, page 8. International Trade in Fertilisers and Chemical Products, 14. Studies on Pagopyrismus and similar Affections, 54. Cost of Fuel used by Tractors for Ploughing, 83. Wintering of Bees in Ontario, 670. Report on Irrigation Surveys and Inspections 1916-17. 734. Selection of Wheat in Ontario, 749. ### III. — PLANT DISEASES

#### A) INDEX OF SUBJECTS.

- ABIES:** In Oregon: *A. amabilis*; *Cryptophalus amabilis*, and *C. grandis*, 114. *A. grandis*; *Eccoptogaster*, n. sp., *Gnathotrichus sulcatus*, *Hylesinus granulatus*, *Pityoktaines jaspersi*, *Pityophthorus*, n. sp., *Platypus wilsoni*, 114. *A. lasiocarpa*; *Crypturgus* sp., *Pityoktaines laticollis*, and *Pseudohylesinus jaspersi*, 144. *A. nobilis*; *Gnathotrichus sulcatus*, *Phloeosinus cristatus*, *Pityophthorus*, n. sp., *Platypus wilsoni*, *Pseudohylesinus laticollis*, and *Ps. nobilis*, 114.
- Absorption and other Modifications of Certain Fertilising or Anticryptogamic Compounds in Various Natural and Artificial Soils**, 130.
- Abyssinia:** Fungi, 477.
- Acacia:** *A. dealbata*; *Icerya purchasi* in Ceylon, 245. *A. decurrens*; *Aspidiotus camelliae* in Brit. E. Africa, 242. *I. purchasi* in Ceylon, 245. *A. longifolia*; *Aleurocanthus hirsutus* and *Al. T.-signatus* in Australia, 933. *A. Richii*; *Septobasidium Acaciae*, in Japan, 705. *Acacia* sp.; *Aphis laburni* in S. E. Russia, 1180. *Aspidiotus (Chrysomphalus) aurantii*, in S. Africa, 242. *Ceroplastes africanus*, *C. ugandae* and *Stictococcus coccineus*, in Uganda, 243.
- Acalypha:** *Inghisia conchiformis* in Uganda, 243.
- Acanthoscelides obtectus:** Disinfection of Dwarf Beans infested with this Coleoptera, 605. Geographical Distribution, and Description, Morphological and Biological, of the Insect. Attacks on; — Dwarf Bean, (*Phaseolus vulgaris*), Scarlet Runner (*Ph. multiflorus*), Cow Pea, (*Dolichos melanophthalmus*), *Vicia Faba*, Common Vetch, (*Vicia sativa*), Lupin, (*Lupinus albus*), Chickling Vetch (*Lathyrus sativus*), Garden Pea, (*Pisum sativum*) and Maize. Natural Enemy; *Pediculoides ventricosus* in Italy, 606.
- Acer:** *A. grandidentatum*; *Exouscus Aceris* in Utah, 103. *A. macrophyllum*; *Cercospora aceris*, and *Septoria samarae-macrophylli* in Washington, 103. *Gnathotrichus* sp. and *Procrisphalus aceris*, in Oregon, 114. *A. Negundo* (= *Negundo aceroides*) and *A. Pseudoplatanus*; Observations on Damage done to Trees by Tarring streets of Milan (Italy), 584.

- Acetylene Gas: Control of Field Mice in Greece, 949.
- Achatina ponderosa*: Attacks on Tobacco, in Mauritius, 942.
- Acidity, Sap: Resistance of Plants to Disease and Parasites, 630.
- Acothanthura*: *A. spectabilis*; *Physothrips kellyanus*, in Queensland, 937. *Acothanthura* sp.; *Lecanum* (*Saissetia*) *cuneiformis*, in Brit. E. Africa, 242.
- Acrobasis hebesella*, and *A. nebulosa*: Attacks on Pecan Nuts, in U. S. A., 190.
- Acropyga gowdeyi* with *Pseudococcus citri*: On roots of Coffee Plants in Uganda, 243.
- Actinodoths Piperis*: On Leaves of *Piper retrofractum* and *Piper* sp., in the Philippines, 587.
- Actinonema Rosae* (Ros Blotch Fungus): Life History, in Great Britain, 1296.
- Adiantum: *Lecanum* (*Saissetia*) *hemisphaericum*, in Uganda, 242.
- Adversities, Meteorological: Resistant Plants obtained by Selection, 519.
- Accidium*: *Acc. Cassiae*; On Cassia Tree in Singapore (Malacca), 1173. *Acc. Dissotis*, 228. *Acc. elatunum*; On Pine, 1219. *Acc. Gossypii*, Cotton Rust in Texas, 470.
- Acnastella africa*, Parasite of *Tachardia deweyella*, in Uganda, 243.
- Aesculus carnea* (= *Aesc. glabra*) and *Aesc. Hippocastanum*: Damage done to Trees by Tarring Streets of Milan, Italy, 584.
- Africa: Aphides, 487. Fungi, 228, 1295. Fungi of Abyssinia and of Eritrea, 477. Scale Insects (*Coccidae*), 242, 243, 244.
- Africa Brit. E.: *Aleyrodidae*, 933. *Coccidae*, 242, 243.
- Africa, South: *Aleyrodidae*, 933. *Coccidae*, 242. *Uromyces pedicellatus*: On *Eragrostis abyssinica* (= *Poa abyssinica*) and *E. curvula*, in Transvaal, 1427. Status of Introduced Coccids, in 1917, 244.
- Agathis varipes*: Natural Enemy of *Coleophora fuscedinella*, in Sweden, 615.
- Agave: *Ceroplastes ceriferus* in Uganda, 243.
- Agelastica alni*: Injurious to Forest Trees in Sweden, 718.
- Agonoderus pallipes*, 1431.
- Agricultural Legislation: International Yearbook, 7th Year (1916): Protection of Plants against Disease in Victoria (Austr.), Egypt, France, Italy, and Sudan, 1.
- Agriolimax*: *A. agrestis*; Attacks on Market Gardens in New York State, 943. *A. campestris*; On *Phorodon mahaleb*, 943.
- Agriotes lineatus*: Injurious to—Oats, Barley, Wheat, Rye, Beet, Potato, Cabbage, Turnip, Carrot, Onion, Viper's Grass, Cucumber, Salad, Garden Strawberry, Parsnip, Asparagus in Sweden, 241. *A. manicus* (?); On Potato in New York State, 943.
- Agromyza abiens*: On Artichokes in Hérault, 366.
- Agropyron repens*: On Cereals in Montana, 639. *A. Smithii*, 592.
- Agrostis segetum*: On Cereals in Sweden, 241.
- Ailanthus glandulosa*: *Gloeosporium Ailanthi* in Louisiana, 103.
- "Akersorken" (*Microtus agrestis*), 241.
- "Akersnegl" (*Limax agrestis*), 476.
- Alabama: *Aleyrodidae*, 933.
- Alaska: *Autographa californica*, 1062.
- Alberta (Canada): *Autographa californica*, 1062. *Rhagoletis pomonella*, 122.
- Albizzia* sp: *Coccus elongatus* in Uganda, 243.
- Albugo candida* (= *Cystopus candidus*) White Rust; On Cultivated Cruciferae in U. S. A., 594.
- Alces alces*: On Forest Trees, 241.

*Aleurobus* : *A. barodensis*; On *Saccharum officinale* in India, 933. *A. flavus*; On Unknown Tree and on *Loranthus* in Ceylon, 933. *A. marlatti*; On Orange in Japan, 933. *A. olivinus*; On Olive in Italy, 933. *A. philippinensis*; On Unknown Tree and on *Murraya exotica* in the Philippines, 933. *A. setigerus*; On *Harpullia pendula* and on Unknown Host in Ceylon, 933. *A. simulus*; On *Bombax malabaricum* in India, 933. *A. solitarius*; On *Cercis canadensis* in Illinois, 933. *A. taonabae*; On *Taonabo japonica* and on Vine in Japan, 933.

*Aleurocanthus* : *A. bambusae*; On *Bambusa* in India, 933. *A. banksiae*; On *Banksia integrifolia* and *Callistemon linearis* in Australia, 933. *A. calophylli*; On *Calophyllum neophyllum* in Fijii, 933. *A. citricolus*; On *Citrus* sp. in Brit. E. Africa, 933. *A. citriperdus*; On Unknown Tree and Orange in Ceylon, India and Java, 933. *A. dissimilis*; On Unknown Vine, at Mirdon, Lower Burma, 933. *A. hirsutus*; On *Acacia longifolia* in Australia, 933. *A. longispinus*; On *Bambusa* in India, 933. *A. mangiferae*; On Mango in India, 933. *A. nubilans*; On Piper Beetle in India, 933. *A. piperis*; On *Piper nigrum* (?) in India, 933. *A. serratus*; On Unknown Tree in Java, 933. *A. spiniferus*; On *Citrus* sp. and *Rosa* in Java, 933. *A. spinosus*; On Unknown Host in Formosa, 933. *A. T. signatus*; On *Acacia longifolia* in Australia, 933. *A. voeltzkowi*; On Un named Plant in Madagascar, 933. *A. woglumi*; In W. Indies and Bahama Islands, 933. On Various Cultivated Plants in Cuba, 1186.

*Aleurocybotus* : *A. setiferus*; On *Imperata* at Java, and on Grass in Ceylon, 933. *A. graminicolus*, 933.

*Aleuroparadoxus*; *A. iridescens*; On *Arctostaphylos* sp. in California, 933. *A. punctatus*; On *Lithraea caustica* and *Quillaja Saponaria* in Chile, 933.

*Aleuroplatus* (*Aleuroplatus*): *A. berbericolus*; On *Berberis Aquifolium* in Brit. Columbia and on *Ilex* in Mexico, 933. *A. coherelli*, 933. *A. cococolus*; On Coconut in Cuba and in Trinidad; On *Eugenia Michellii* in Brazil; also found in Panama, 933. *A. coronatus*; On Chestnut, on Unknown Plant, and on *Quercus agrifoliae* in California, 933. *A. euryae*, 933. *A. ficus rugosae*; On *Ficus rugosa* in India, 933. *A. gelatinosus*, 933. *A. incisus*; On Unknown tree, *Garcinia spectabilis* and *Ostodes zeylanica* in India, 933. *A. myricae*; On *Myrica* sp (?) in Georgia, 933. *A. oculiminitus*; On *Ficus* sp. in Trinidad, 933. *A. oculvreniformis*; On *Passiflora* in Brazil, 933. *A. ovatus*; On *Berberis trifoliata* in Texas, 933. *A. pectiniferus*; On *Morus* sp. in India, 933. *A. plumosus*; On *Vaccinium* spp. in Florida, New Jersey and Wisconsin, 933. *A. quercus-aquaticae*, 933. *A. sculpturatus*; On *Heliconia* in Panama, 933. *A. translucidus*; On Orange in India, 933. *A. validus*; On Unknown host in Jamaica, 933. *A. variegatus*; On *Psidium* sp., in Costa Rica, 933. *A. vinsonioides*; On *Nectandra* in Cuba, 933.

*Aleuroplatus* (*Orchamus*): *A. mummaeferus* n. sp.: On *Codiaeum variegatum* at Java, 933.

*Aleurothrixus* (*Aleurothrixus*): *Aleur. aëpim*; On *Manihot utilissima* in Rio de Janeiro, 933. *A. floccosus*; On "lignum vitae" from Jamaica; On Guava from Brazil; On Orange in Mexico: also on *Baccharis genistelloides*, *Citrus* spp., *Coccoloba*

- uvifera*, *Plumeria* sp., etc., found in Argentina, Chile, Costa Rica, Florida, British Guiana, Paraguay, 933. *A. howardi*; On Same Hosts and in the Same Localities as the Preceding Species; Reported for the First Time in U. S. A. on *Coccoloba uvifera* (Sea Grape) in Florida, 933. *A. porteri*; On *Citrus* in Chile, 933.
- Aleurothrixus* (*Philodamus*) *interrogationis*, 933.
- Aleyrodidae*: On Various Plants in Different Countries, 933.
- "Alfalfa Looper" (*Autographa californica*), 1062.
- Algeria: *Chilocorus bipustulatus*, 828. *Gelechia gossypiella* on Cotton, 865.
- "Algullbäggen" (*Mesaspasma aenea*), 718.
- "Allonhorren" (*Melolontha* sp.), 241.
- Allothrombidium gymnopterorum*: Nat. Enemy of *Chrysomphalus dictyspermi*, *Diaspis pentagona* and other *Diaspinae*, 118.
- Almond: *Olethreutes variegana* in Italy, 611. Locust attacks in the Capitanata (Italy), 1311. "Verdesseco" of Fruit Trees in Apulia, Italy, 597.
- Alnus: *A. Oregana*; Host of *Gnathotrichus* sp., in Oregon, 114. Attacks by *Hylesinus aspericollis* in Oregon, 114. *A. rubra*; Attacked by *Cercospora alni* (?) in Washington, 103.
- Alœ margaritifera* (= *Haworthia margaritifera*): Observations on Damage done by Tarring Streets of Milan, Italy, 584.
- Alsophila pomataria* (Fall Canker Worm): On Apple, Cherry and Plum Trees in Ontario, 247.
- Alternanthera*: *A. echinata*, 932. *A. versicolor*; *Pulvinaria psidii* in Uganda, 243.
- Alternaria Brassicae*: On Cultivated Cruciferae in U. S. A., 594.
- Amaranthus retroflexus*: Amongst Cereals in Montana, U. S. A., 639.
- Amaurosoma* (*Cleigastira*) *armillatum* and *A. flavipes*: On Seed of *Phleum* in Sweden, 241.
- Amblyteles nunciu*s and *Ambly. subfuscus*: On *Euxoa excellens* in British Columbia, 1062.
- Amaebosporidia* (?): On *Orycaerus hyalinipennis* in Italian Somaliland, 1184. *Ameloclonus* sp.; Nat. Enemy of *Autographa californica* in Brit. Columbia, 1062.
- America: *Aspidiotiphagus citrinus*; Nat. Enemy of *Chrysomphalus dictyspermi*, 118. Coccids, 242. Cynipidae, On *Castanopsis* spp., and *Quercus* spp., 124. Fungi, 103. *Ptychoaes irilineatus*, (Three-Lined Fig-Tree Borer), 248. *Macrosiphon illinoisensis*, Grape Vine Aphis, 367. N. America: *Uromyces Eragrostis* on *Eragrostis pectinacea*, 1427. S. America: Uredinales of the Andes, 926. Tropical and Sub-Tropical America: Diseases of Sugar Cane, especially in West Indies, 1057.
- Amphibolips nigra*: On *Quercus* sp. in Mexico, 124.
- Amphiscepa bivittata*: On *Oryctococcus macrocarpus*, in U. S. A., 495.
- Amygdalus tangutica*: Very resistant to Drought and Cold in China, 1086.
- Anastatus bifasciatus*: On *Portia dispar* (Gipsy Moth) in Spain, 1432.
- Andes: Uredinales collected in 1914, 926.
- Andricus*: *A. castanopsidis*; On Flowers of *Castanopsis sempervirens* and *C. chrysophylla* in California, 124. *A. dugesi* in Mexico, 124. *A. gemmiformis*; On Trunk of *Quercus alb.* in New Jersey, New York City and Illinois, 124.
- Andropogon*: *A. annulatus*: Common

- Weed in Sindhi, (India) 484. *A. Sorghum* (= *Sorghum vulgare*): Smuts in Pres of Bombay, 1054.
- Angitia* sp: Nat. Enemy of *Coleophora fuscedinella* in Sweden, 615.
- "Angstinkflyet" (*Lygus pratensis*), 241.
- Anisandrus* (*Xyleborus*, *Scolytus*, *Tomicus*) *dispar*; On Fruit Trees in Sweden, 241.
- Anona muricata*: In Uganda, *Aspirotus gowdeyi*, *Ceroplastes ceriferus*, *C. quadrilineatus* and *C. ugandae*, *Inghisia conchiformis*, *Saissetia nigra*, and *Stictococcus diversiseti*, 243. *Tachardius decorella*, 242, 243. *T. longisetosa*, 243. *Anona* sp.; *Ceroplastes ficus* at on Gold Coast, 242.
- Anthaxia aurulenta*: On Elm and *Salix alba* in Hérault, 602.
- Anthrenomus*: *A. grandis*, 488. *A. pomorum*; On Fruit Trees in Sweden, 241. *A. rubi*; On Strawberries and Raspberries, in Sweden, 241.
- "Anthracnose": Of Chick Pea, ("Rabbia"): *Phyllosticta Rabiei*, Specific Agent, 1177. Of Water Melon, (*Colletotrichum lagenarium*), 238. Of Vine: Resistance of Hybrid Bearers in France, 303, 770.
- Anti-cryptogamic Compounds: Absorption and other Modifications of certain Fertilising or "A-c" Compounds in Various Natural and Artificial Soils, 130. Spanish Mineral Products, 509.
- Antigonon leptopus*: *Ceroplastes ceriferus* in Uganda, 243.
- Antigua: *Euscepes batatae*; On Sweet Potato, 936.
- Antilles: *Acanthoscelides obtectus*, 606. *Aleyrodidae*, 933. Chalcids 934. Diseases of Sugar Cane, 1057. *Hevea brasiliensis* attacked by S. American *Hevea* Leaf Disease (*Scolecotrichum* sp.) in Trinidad, 236. Government
- Order of Colony of Trinidad and Tobago placing the Coconut Butterly (*Brassolis sophorae*) among Plant Pests, 1171. *Odontia Saichari*; On Sugar Cane *O. saicharicola*; On Sugar Cane and on Paspalum in Porto Rico, 1176. *Pachymerus quadrimaculatus*; On Black-Eye Pea (*Vigna catjang*) in Trinidad, 1182. *Tomaspis saccharina*: On Sugar Cane in Grenada and Trinidad, 939. Varieties of Cotton Plant immune to Black Scale, *Saissetia nigra* in St. Vincent, 117.
- Antirrhinum*: *Cercospora Antirrhini* in Great Britain, 1124.
- Ants, White: On Cacao: in Princes Island, and São Thomé, 609. On Pecan, in U. S. A. (especially *Leucotermes flavipes*), 196. On Tobacco, in Mauritius, 912. On Citrus in Dutch Guiana, 300. Nat. Enemy: Of *Aleurocanthus woglumi* in Cuba, 1186. Of *Lonchaea aristella* in Italy, 716.
- Amiraphis persicae*, 650
- Aonidia lauri*: *Aspidiotiphagus citrinus*, 118.
- Aonidiella auranti* var. *citrina*, and *A. perniciosus*: *Aspidiotiphagus citrinus*, 118.
- Apamea testacea*: On Gramineae in Sweden, 211
- Apanteles*: *A. corvinus*, *A. musoxanthus* *A. sodalis* (?), *A. xanthostigmus* and *Apanteles* sp. Nat. Enemies of *Coleophora fuscedinella* in Sweden, 615. *A. hyslopi*; Nat. Enemy of *Autographa californica* in Brit. Columbia, 1062. *A. lactescens*; On *Eupioctis chrysorrhoea* imported into U. S. A. from Europe, 1433. *A. longicauda*; On *Olethreutes variegata* in Italy, 611.
- Aphelinus*: *A. boveii*: On *Chrysomphalus dictyospermi* in Barbados, 1059. *A. chrysomphali*, Nat. Enemy

- of *Chrys. dictyospermi* in Spain and of *Aonidiella aurantii* in Greece, 118. *A. silvestrii*, Nat. Enemy of *Chrys. dictyospermi* in Italy, 118.
- Aphicus*: *A. flavidulus* var. *caridei* and var. *nigra*, Nat. Enemies of *Pulvinaria flavescens*, *P. minuta* and *P. platensis* in Argentina, 1308. *A. hesperidum*, Nat. Enemy of *Chrysomphalus dictyospermi* in Spain, 118.
- Aphididae*: In Africa, 487. Injurious to Alfalfa in the Oasis of Tripoli, 173. In S. E. Russia, 1180.
- Aphidus brasiliensis*: On Aphids in S. Brasil, 714.
- Aphis*: *A. acetosae*; On *Papaver* spp. and on *Rumex* spp in Egypt: also in England and Germany, 487. *A. avenae*; On Cereals in Norway, 476. *A. avenae* (European Grain Aphis), in Ontario, 247. *A. bauhinniae*; On *Bauhinia* in Egypt, 487. *A. buddleiae*; On *Buddleia mada-gascariensis* in Cairo, 487. *A. cardui* (= *A. myosotidis*); On Thistle in S. E. Russia, 1180. *A. durantae*; On *Duranta* in Egypt, 487. *A. ficus*; On *Ficus Sycomorus* in Egypt and Uganda, 487. *A. laburni*; On *Acacia*, *Chenopodium*, *Medicago*, *Melilotus officinalis* and *Sambucus* in S. E. Russia, 1180. *A. matthio-lae* and *A. matthioellae*; On Ornamental Stock in Egypt, 487. *A. A. myosotidis* (= *A. cardui*); On Thistle in S. E. Russia, 1180. *A. persicae*, 630. *A. pheidole* associated with Ants, (*Pheidole* sp.) in Rhodesia, 487. *Aphis* sp (?); On *Euphorbia* and on *Nigella*, in S. E. - "Bramble Leaf Disease": Chasselas × Berlandieri 41B. Resistant Vine Stock in Sicily, 873.
- Bran, Poisoned: Control of Locusts in Capitanata, 1311.
- Brassica: *B. arvensis*; Host of *Myzus cerasi* in Ontario (?), 368. Amongst Cereals in Montana, 639. *B. Napus*; *Siphocoryne* (*Aphis*) *pseudobrassicæ* in U. S. A. and S. Africa, 487. *B. oleracea*; *Aphis* (*Siphocoryne*) *pseudobrassicæ* with *Rhopalosiphum dianthi* in Egypt, 487. *B. O*; *Rhopalosiphum dianthi* with *Aphis brassicæ* in Egypt, 487. *B. O. var. acephala*; *Siphocoryne* (*Aphis*) *pseudobrassicæ* in U. S. A. and S. Africa, 487. *B. o. f. Botrytis*; Spot Disease of Cauliflower in U. S. A., 594. *B. o. bullata major*; *Aphis* (*Siphocoryne*) *pseudobrassicæ* with *Rhopalosiphum dianthi* in Egypt, 487. *B. Rapa* var. *depressa*; *Siphocoryne* (*Aphis*) *pseudobrassicæ* in U. S. A. and S. Africa, 487.
- Brassolis sophoræ*: Order of Government of Colony of Trinidad and Tobago placing the Coconut Butterfly among Plant Pests, 1171.
- Brazil: *Acanthoscelides obiectus* and *Spermophagus subfasciatus*; Attacks on Dwarf Beans, 605. *Aleyrodidae*, 933. *Cercospora solanicola*: On Tobacco and *Cercospora* sp.: On Sesame, in Pernambuco, 1058. *Euscepes batatae*; On Sweet Potato, 936. Fungi, 586. Hymenoptera Parasitic on Injurious Insects, in S. Brazil, 714. Insect and Vegetable

- Parasites of Cacao Tree in Bahia, 493. *Macrosiphon illinoisensis* (?) Grape Vine Aphis at Campinas, 367. *Breweria Burchellii*: *Puccinia Simasii* in Brazil, 586.
- British Columbia: *Aleyrodidae*, 933. *Autographa californica*; On Various Cultivated Plants, 1062. *Euxoa excellens*; On Many Varieties of Vegetables, 494. *Rhagoletis pomonella*, Apple Maggot recorded for First Time in B. C.
- Broad Leaf Burley, Variety of Tobacco attacked by Root Rot (*Thielavia basicola*) in Ireland, 1916, 49.
- Brown Rot of Cruciferae (*Bacterium campestris*), 594.
- "Brusone" *Fusicladium pirinum* var. *Eriobotryae*; On Japanese Medlar, 599, 826.
- Bucculatrix thurberaella*: *Arthrolytus aenoviridis* obtained from *B. t.* on Cotton in Arizona, 934.
- Buddleia madagascariensis*: *Aphis budleiae* in Egypt, 487.
- Bud Moth (*Imetocera ocellana*), 247.
- Buffalo Tree Hopper (*Ceresa bubalus*), 247.
- Bupalus piniarius*: On Forest Trees in Sweden, 718.
- CABBAGE: *Agriolimax agrestis* in State of N. York, 643. *Agriotes lineatus*; *Chorthophila* (*Phorbia*) *brassicae*, *Eurydema oleracea*, *Lygus pratensis*, *Phyllotreta* sp., and *Plutella maculipennis* in Sweden, 241. *Autographa californica*, In Brit. Columbia, 1062. *Barynotus squamosus*, in Norway, 476. *Perezia legeri*, Protozoan Parasite of Larvae of *Pieris brassicae*, 603. *Per. mesnili*, Parasite of Larvae of *Pieris brassicae* in France, 370. *Pimpla alternans*, Parasite of *Pieris brassicae*, In Hérault, 366. *Rhytidoderes plicatus*, In Hérault, 622. *Scapteriscus vicinus*, In Porto Rico, 1063.
- Cacao: African Variety resistant to *Ephestia elutella*, 519. *Aspidiotus palmarum*, In São Thomé, 609. *Heliobasidium longisporum*, In Uganda, 228. *Inglisia castilloae* var. *theobromae*, In Uganda, 243. Insect Parasites, In São Thomé, 609. Insect and Vegetable Parasites, In State of Bahia (Brazil), 493. *Microcerotermes parvus* subsp. *theobromae*, In São Thomé, 609. *Neotermes gestri*, In São Thomé, 609. *Pseudococcus citri*, In Uganda, 243. *Ps. virgatus*, In S. Nigeria, 242. *Stictococcus diversiseti*, In Uganda, 243. *St. sjöstedti*, On Gold Coast, 242.
- "Çaçarema", *Dolichoderus bituberculatus* (?), 493.
- Cacti: *Pseudococcus longispinus* var. *latipes*, in Manchester (Engl.) 485.
- Cajanus indicus*: *Ceroptastes africanus*, *C. vinsonioides*, *Coccus elongatus*, and *Stictococcus diversiseti*, In Uganda, 243.
- Calamagrostis scabra*: *Fusoma rubricosa* in Montana, 103.
- Calandra oryzae*: Pest in Stored Food Stuffs in Java, 1438.
- California: *Aleyrodidae*, 933. *Autographa californica*, 1062. *Phthorimaea operculella*; On Potatoes, 1183. *Rhagoletis pomonella*, (Apple Maggot), 122. *Stenomacoccus plutani*; On *Platanus racemosa*, 123. *Tilletia Wilcoxiana*; On *Stipa eminens* var. *Andersonii* in Santa Catalina Is., 228.
- Callimorpha dominula*: On Elm and Ash in Sweden, 241.
- Calliptamus*: In Capitanata (Italy), 1311.
- Callistemon linearis*: *Aleurocanthus banksiae*, In Australia, 933.
- Calodendrum capensis*: *Cerococcus ornatus*, In S. Africa, 244.
- Calophyllum*: *C. Burmanni* ("guru-kina") *Hypochnus* sp. in Ceylon,

109. *C. neophyllum*: *Aleurocanthus calophylli* in Fiji, 933.
- Camellia sativa*, (False Flax); Amongst Cereals in Montana, 639.
- Camphor: *Tylenchus penetrans* in Florida, 491.
- Camponotus*, 366.
- "Caña blanca", Sugar Cane subject to Disease in Porto Rico, 1239.
- Canada: *Autographa californica*; On Various Cultivated Plants, 1062. Common Pests of Fruit Trees in Ontario, 247. *Euxoa excellens*; On many Varieties of Vegetables in Brit. Columbia, 494. *Lepidum apetalum*, Secondary Host of *Myzus cerasi* (living also on *Brassica arvensis*, *Capsella Bursa-pastoris* and *Erysimum cheiranthoides*) in Ontario, 368. Principal Diseases of Vegetables in Ontario, 709. *Rhagoletis pomonella*, Apple Maggot, recorded for the First Time in Brit. Columbia, 122. *R. p.* observed in Alberta, 122.
- Canary Island: *Acanthoscelides obtectus*, 606.
- Canis zerda*, Fennec Fox: Destroyer of Injurious Insects and Animals, 1266.
- Canna indica*: Observations on Damage done to Trees by Tarring Streets of Milan, 584. *Canna* sp.; *Ceroplastes ceriferus* in Uganda, 243. *Phyothrips marshalli* on Gold Coast, 937.
- Cannabis sativa*, 228.
- "Cañuela" (*Sorghum halepense*), 1430.
- Cape Province: Coccids introduced in 1917, 244.
- Cape Lilac. Host of *Aspidiotus cydoniae* in Uganda, 242.
- Capnodium*: *C. Coffeae* (?). On Coffee in São Thomé, 609. *C. meridionale*; On Branches of Olive attacked by *Lecanium oleae* in France, 821.
- Capsella Bursa-pastoris*: Host of *Myzus cerasi* in Ontario, 368. Amongst Cereals in Montana, 639.
- Capreolus capreolus*: On Forest Trees in Sweden, 241.
- Capsicum annuum*: *Puccinia paulensis* in Brazil, 586.
- Carduus*: *C. arvensis* and *C. lanceolatus* Amongst Cereals in Montana, 639. *Carduus* sp.; *Aphis cardui* (= *A. myosotidis*) in S. E. Russia, 1180.
- Carica Papaya*: *Aspidiotus articulatus* and *A. palmarum* in São Thomé, 609.
- Carob: *Aspidiotus hederæ* attacked by *Chilocorus bipustulatus* in Algeria, 828.
- Carp: Means of Destroying Weeds in Rice Fields in Italy, 78.
- Carolina: North; *Aleyrodidae*, 933. *Macrosiphum illinoisensis*. Grape Vine Aphid, 367. *Tylenchus penetrans*; On Upland Cotton, 491. South; *Ptychodes trilineatus*; On Fig, 248.
- Carpocapsa*: *C. pomonella*; Campaign against Codlin Moth in Cyprus in 1917: 612: On Apple and Pear in Ontario, 247; On *Diospyros Kaki*, *D. Lotus*, etc. in Hérault, 366: On Fruit Trees in Sweden, 241. *C. splendana* (?); On Chestnuts in Italy, 1066.
- Carpophilus* spp.: Pest in Stored Food-Stuff in Java, 1438.
- Carrot: *Agriotes lineatus*, *Psila rosae* and *Trioxa viridula* in Sweden, 241. *Autographa californica* in U. S. A. 1062. *Phytoecia cylindrica* in Sweden, 121. *Pseudomonas destructans* in Norway, 476.
- Carya olivaeformis* (Pecan): Attacks by Insects in U. S. A., 496. *Nezara viridula* and Kernel Spot, (C.o) caused by *Coniothyrium caryogenum* in Georgia, U. S. A., 927.
- Casca luzonica*: Endophagous on *Schizaspis lobata* in the Philippines, 1060.
- Casnonia pennsylvanica*: Enemy of *Blissus leucopterus* in Illinois, 1431.

- Cassia*: *C. floribunda*: *Aulacaspis chionaspis* and *Chionaspis cassiae* in Uganda, 243. *C. Fistula*; *Meliola aethiops* in Singapore, 1173. *C. Tora*: *Aecidium Cassiae* in Singapore, 1173.
- Cassida*, 1315.
- Castanopsis chrysophylla* and *C. semipervirens* attacked by *Andricus castanopsidis* on California, 124.
- Castilleja*: *Icerya sulphurea* in Uganda, 242, 243.
- Castor Oil*: *Aspidiotus destructor* in Zanzibar, 242; and see *Ricinus*.
- Cauliflower*: *Agriolimax agrestis* in N. York State, 943.
- Cecidomyidae*: On *Olea chrysophylla* in Eritrea, and on *O. europaea* in Italy, 945.
- Cecidomyia aurantiaca*: On Wheat in Norway, 476.
- Cedrela Toona*: *Hemilecanium imbricans* in S. Mysore, 242.
- Cedrus*: *C. Deodara* attacked by Unidentified Fungus in India, 483. *C. Libani* attacked by *Pseudohylestinus* n. sp. in Oregon, 114.
- Celastrus buxifolius*: *Dialeurodes (Gigaleurodes) cerifera* in S. Africa, 933.
- Celery*: *Linus iridis* in Hérault, 366.
- Celtis australis*: New Disease in Italy, 1293.
- Cenangium urceolatum*, 237.
- Centaurea*: *Macrosiphum sonchi* in S. E. Russia, 1180.
- Cephalosporium*: Fungus controlling *Icerya purchasi* in Ceylon, 245. *C. Lecanii*, Nat. Enemy of *Lecanium viride* in São Thomé, 609. *C. Sacchari*; On Sugar Cane in Tropical and Sub-tropical America, especially the W. Indies, 1057.
- Cereals*: *Agriotes lineatus*, *Agrotis segetum*, *Contarinia tritici*, *Hylemyia coarctata*, *Melolontha* sp., *Oscinella (Oscinis) frit*, *Siphonella (Chlorops) pumilionis* in Sweden, 241. *Aphis avenae* in Norway, 476. Cold (Resistance to); Relation of Density of Cell Sap to Winter Hardiness in Small Grains in U. S. A., 1217. Cold, Lodging and Rust, Resistance to, in Sweden, 143. Effect of Low Temperature on Winter and Spring Grain in U. S. A., 257. *Erysiphe* in Norway, 476. *Macrosiphum granarium* in Norway, 476. *Pleospora* and *Puccinia* in Norway, 476. Rust on Cereals, particularly Black Rust on Wheat (Australian Interstate Conference of Agricultural Scientists), 1076. *Thrips denticornis*, *Tilletia*, *Ustilago* in Norway, 476. Worst Weeds in Montana, 639.
- Ceratophyllus*: On Field Mice in Italy, 1318.
- Ceratocarpia Cactorum*: On Fig and Orange in France, 821.
- Cercis canadensis*: *Aleurolobus solitarius* in Illinois, 933.
- Cercopidae*, 939.
- Cercospora*: *C. beticola*, 1315. *C. canabina*; On *Cannabis sativa*, in Uganda, 228. *C. Genipae*; On *C. Genipa* sp. in Brazil, 586. *C. Kopkei*; On Sugar Cane in Tropical Africa, particularly West Indies, 1057. *C. latimaculans*; On *Bauhinia* on the Gold Coast, 1295. *C. personata*; On *Arachis hypogaea* in the Philippines, 587; On Peanut in S. China, U. S. A., India, W. Indies and Philippines, 350. *C. Pini-densiflorae*; On *Pinus densiflora* in Japan, 705. *C. Raciborskii*; On *Nicotiana* sp. in Eritrea, 477. *C. solanicola*; On Tobacco in Brazil, 1058. *C. ruginae*; On Sugar Cane in Tropical Sub-tropical America, particularly, W. Indies, 1057. *Cercospora* sp.; On Sesame in Brazil, 1058.
- Cercosporella*: *C. Aceris*; On *Acer macrophyllum* in State of Washington, 103. *C. Alni*; On *Alnus rubra* in State of Washington, 103. *C. An-*

- tirrhini*; On *Antirrhimum* in Great Britain, 1424. *C. Pastinacae*; On Parsnip in England 825.
- Ceresa bubalus*: On Apple, Cherry, and Plum in Ontario, 247.
- Cerococcus*: *C. hibisci*; On Egg Plant in S. India, 242. *C. ornatus*; On *Calodendrum capensis* and *Doryalis caffra* in S. Africa, 244.
- Ceroplastes*: *C. actinoformis*; On Coconut in Coimbatore, 242. *C. africanus* in S. Africa; On *Acacia* sp., 242 and *Cajanus indicus*, in Uganda, 243. *C. ceriferus*; On *Agave*, *Anona muricata*, *Antigonon leptopus*, Coffee, *Canna*, *Codiaeum*, *Ficus Thonningii*, *Funtumia latifolia*, *Hibiscus*, Orange and Tea, in Uganda, 243. On Wild Elm, Coimbatore, 242. *C. cirripediformis*; On *Hura crepitans* with *Lecanium* (*Akermes*) sp. in Brit. Guiana, and on *Ipomoea* sp., Georgetown, 242. *C. conchiformis*; On *Anona muricata*, *Acalypha*, *Harcnga madagascariensis* and *Hibiscus* in Uganda 243. *C. conformis*; On *Ficus* sp. and *Hura crepitans* in Uganda, 243. *C. destructor*; On *Psidium Guajava* in Uganda, 243. *C. denudatus*; On a Wild Solanaceae in Brit. Guiana, 242. *C. ficus*; On *Ficus Thonningii* in Uganda, 243. On *Ochra pulchella* in S. Africa, On *Anona* on the Gold Coast, 242. *C. galeatus*; On Coffee and *Ficus Thonningii* in Uganda, 243. *C. personatus*; On *Coffea liberica* on the Gold Coast, 242. *C. quadrilineatus* in Uganda, 242. *C. q.* on *Anona muricata* and *Dolichandrone platycalyx* in Uganda, 243. *C. rubens*; On Mango, S. India, 243; On Oranges in Zanzibar, 242. *C. ruscii*; On Fig in Algeria, 828, On Fig in France, 821. *C. sinensis*, 828. *C. singularis*; On *Psidium Guajava* in Uganda, 243. *C. subdenudatus* with *Stictococcus coccineus*; On *Acacia* sp. in Uganda, 243. On Undetermined Plant in Uganda, 243. *C. ugandae*; On *Acacia* sp. and *Anona muricata* in Uganda, 243; On Unknown Tree in Uganda, 242. *C. vmsomodes*; On *Baikraea Eminii*, Coffee, *Cajanus indicus* and *Psidium Guajava* in Uganda, 243. On Coffee in Uganda, 242.
- Ceroplastodes*: *C. cajani*; On *Vigna Catjang*, *Zizyphus*, *Ocimum sanctum* in Coimbatore; on *Indigofera* in S. India, 242. *C. gowdey*; On *Ficus Thonningii* in Uganda, 243.
- Ceylon: *Aleyrodidae*, 933. Fungi, 704. *Hypochnus* sp.; On Tea, 109. *Icerya purchasi*; On *Acacia dealbata*, *A. decurrens* and on Citrus, 245. Myxomycetes, 704. *Septogloeum Arachidis*; On Peanut, 350.
- "Chabar" (*Cynodon Dactylon*), 484.
- Chaetochloa viridis*: Weed injurious to Cereals in Montana, 639.
- Chalcids, West Indian and N. American, 934.
- Chamaecypris*: *C. Lawsonsiana*; *Phloesinus punctatus* in W. Oregon, 114. *C. nootkatensis*; *Phloesinus dentatus* and *Ph. punctatus* in W. Oregon, 114; On *Phloesinus cristatus* at Elk Lake, (Oregon), 114. *C. thyoides*: *Keithia Chamaecypris* in New Jersey, 1307.
- Chamaerops humilis*: *Derolomus chajava maeropsis* in Hérault, 602.
- Chamus*: *C. bellus*; On "lionzi" and *Ch. tuberculatus*; On *Psidium Guajava* in the Belgian Congo, 940.
- "Changa" (*Scaptieriscus vicinus*), 1063.
- Charaxes jasius*: On Strawberry Tree (*Arbutus Unedo*) in Hérault, 366.

- Drouthspot on Apples, 1018
- Dryophanta floridensis*: On *Quercus digitata* and *Q. brevifolia* in Florida, 124.
- Dryocoetes*: *D. autographus* and *D. pseudotsugae*; on *Pseudotsuga taxifolia* in Oregon, 114.
- Dry Rot (*Bacterium campestris*, *Fusarium conglutinans*): On Cultivated Cruciferae, 591.
- "Dubh" (*Lragrostis cynosuroides*), 484.
- "Duke of Albany" Pea, subject to *Pseudomonas seminum* in England, 595.
- Duranta*: *Aphis durantae* in Egypt, 487.
- "Dvaergeikade" (*Cicadula sexnotata*), 1313.
- Dyscinetus trachypygus*: On *Oxyrocus macrocarpus*, in U. S. A., 495.
- Dysdercus scassellatii*: On Cotton in S. Italian Somaliland, 830.
- EAST INDIES, DUTCH: *Lasioderma serricorne* and *Setomorpha marga-laestriata*, On Tobacco, 1436.
- Eccoptogaster*: *E. rugulosus*; On Ap-

- ple, Cherry, Peach, and Pear in Ontario, 247. *E. subscaber*; On *Abies grandis* and *Abies* spp. in Oregon, 114. *E. unispinosus*; On *Larix occidentalis*, *Pseudotsuga taxifolia* and *Picea Engelmanni* in Oregon, 114. *Eccoptyogaster* n. sp.; On *Abies grandis* in Oregon, 114.
- Echevera metallica* (= *Cotyledon gibbiflora*): Observations on Damage done by Tarring Streets of Milan (Italy), 584.
- Egypt: Aphides, 487. *Gelechia gossypiella*, on Cotton, 1356.
- "Ekorren" (*Sciurus vulgaris*), 241.
- Elaphidion villosum*: On Pecan, in U. S. A., 496.
- Elasmus viridiceps*: Nat. Enemy of *Coleophora fuscedinella* in Sweden, 615.
- Eleusine: *E. aegyptiaca* and *E. flagellifera*, Farm Weeds in Sindh, (India), 484. *E. indica* attacked by *Scapteriscus vicinus*, Porto Rico, 1063.
- Elm: *Anthraxia aurulenta*, and *A. manca*, in Hérault, 602. *Callimorpha dominula*, in Sweden, 241. *Choerorrhinus squalidus*, *Exocentrus punctipennis*, *Hylesinus vittatus* and *Scolytus multistriatus*, and *Stromatium fulvum* in Hérault, 602. *Schizoneura ulmi* and *Tetraneura ulmi*, in S. E., Russia, 1180. New Disease in Italy, 1293.
- Empire, British: Pests and Diseases of Rice, 254.
- Enarmonia prunivora*: On Apples in Ontario, 247. On Apples in Sweden, 241.
- Endrot, of Cranberries (*Fusicoccum putrefaciens*), 237.
- Enemies, Natural: *Accogaster quadridentatus*; Of *Olethreutes variegana* in Italy, 611. *Aenasiella africa*, Of *Tachardia decorella*, 243. *Agathis varipes*; Of *Coleophora fuscedinella* in Sweden, 615. *Agriolimax campestris*; Of *Phorodon mahaleb*, 943. *Amblyteles nuncius* and *A. subfuscus*; Of *Euxoa excelsens*, 494. *Amaeosporidia* (?); Of *Oxycaremus hyalinipennis*, in Italian Somaliland, 1184. *Amelocotmus* sp.: Of *Autographa californica* in Brit. Columbia, 1062. *Anastatus bifasciatus*; Of *Porthetria dispar* in Spain, 1432. *Angitia* sp.; Of *Coleophora fuscedinella* in Sweden, 615. Ants: Of *Aleurocanthus woglumi* in Guantánamo, (Cuba), 1186 and of *Lonchaea aristella* in Italy, 716. *Apanteles corvinus*, *A. mesoxanthus*, *A. sodalis* (?), *A. xanthostigmus* and *Apanteles* sp.; Of *Coleophora fuscedinella* in Sweden, 615. *A. hyslopi*; Of *Autographa californica* in Brit. Columbia, 1062. *A. lacticolor*; Of *Euprocitis chrysorrhoea* imported into U. S. A. from Europe, 1433. *A. longicaudis*; Of *Olethreutes variegana* in Italy, 611. *Aphelinus boveii*; *Chrysomphalus dictyospermi* in Barbadoes, 1059. *Aphicus flavidulus* and *A. f.*, var. *nigra*; Of *Pulvinaria flavescens*, *P. minuta*, and *P. platensis* in Argentina, 1308. *Aphidus brasiliensis*; Of Aphids in S. Brazil, 714. Arachnid; Of *Aleurocanthus woglumi* in Cuba, 1186. *Arthryolytus aenoviridis* reared from *Bucculatrix thurberiaella*; Of Cotton in Arizona, 934. *Aschersonia*; Of *Aleurocanthus woglumi* in Jamaica, 1186. *Atoposomoidea ogimae*; Of *Porthetria dispar* in Spain, 1432. *Atidae*; Of *Tomaspis saccharina* in Grenada and Trinidad, 939. *Bacillus* spp. and *Bacterium* spp; Biological Control of Field Mice in Italy, 1316, 1317, 1318. Bacterial Disease: Of *Autographa californica*, in Brit. Columbia, 1062. *Bacterium murisepticum*. Specific Agent of an In-

fections Disease of Field Mice (*Pitymys savii*), in Apulia (Italy), 1187. Bats, Use of, in Control of Insects, especially Tortricidae, Injurious in Pine Woods, 1061. Birds; Of *Autographa californica*, in Brit. Columbia, 1062. Birds, Native: Of *Scapteriscus vicinus* in Porto Rico, 1063. *Blechnus glabratus* and *Bl. pusio*; Of *Blissus leucopterus*, in Illinois, 1431. *Casca luzonica*; Endophagous on Scale Insect, *Schizaspis lobata*, in the Philippines, 1060. *Canis zerda* (Fennec Fox); Of Cockchafers, Locusts, Crickets, and Injurious Insects, 1266. *Casnonia pennsylvanica*; Of *Blissus leucopterus*, in Illinois, 1431. *Cephalosporium*; Of *Icerya purchasi*, 245. *Ceph. Lecanii*; Of *Lecanium viride* in São Thomé, 609. Chalcids, West Indian and N. American, 934. *Chilocorus bipustulatus*; Of Coccidae, 118, 828. *Ch. cacti*; Of *Aleurocanthus woglumi*, in Cuba, 1186. *Chrysocharis elongata*, and *Cirrospilus pictus*; Of *Coleophora fuscadinella*, in Sweden, 615. *Chrysopa*; Of *Blissus leucopterus* in Illinois, 1431. *Closterocerus utahensis* (*Cl. californicus*) One Female obtained from *Symydobius chrysolepis*; Of *Quercus chrysolepis*, in California, 934. Coccinellid; Of *Aphis laburni* in S. E. Russia, 1180; Of *Blissus leucopterus* in Illinois, 1431. *Coccophagus comperei*; Of *Stictococcus gowdeyi*, 243; *C. nigropleurum*; Of *Tachardia decorella*, 243; and *C. saintebeuvei*; Of *Saissetia oleae*, 243. *Copidosoma* sp; Of *Olethreutes variegana*, in Italy, 611. *Dendrosoter protuberans*; Of *Scolytus multistriatus* in Hérault, 602. *Elasmus viridiceps*; Of *Coleophora fuscadinella* in Sweden, 615; *Epilachma punctipennis*; Of *Aspidiotus*

*destructor*, 243; *Epitetrastichus ugandensis*; Of *Stictococcus gowdeyi*, 243. *E. scitula*; Of *Inglisia conchiformis*, 243. *Eumicrosoma benefica*; Of Eggs of *Blissus leucopterus*, 1431. *Eupelmus degeeri*; Of *Rhynchites bacchus*, 374. *Eurytoma galeati*; Of *Ceroplastés galeatus*, 243. In Uganda. *Exorista futilis*; Of *Autographa californica* in Brit. Columbia, 1062. Fleas (Gen. *Ceratophyllus*, *Hystriophsylla* and *Typhlopsylla*): Of Field Mice in Italy, 1318. Fungi: *Aspergillus* and *Penicillium*, Of Field mice, in Italy, 1318. *Geniocerus charoba* and *Glypta* sp.: Of *Coleophora fuscadinella* in Sweden, 615. *Grotiusomyia flavicornis*, reared from a Pyralid Leaf Miner on Oak in Washington, D. C., 934. *G. nigricans*, reared from Larva of *Eudamus proteus* in St. Vincent, 934. *Habrocytus radialis*; Of *Coleophora fuscadinella*, in Sweden, 615. *Hemerobius*; On *Blissus leucopterus* in Illinois, 1431. *Hemiteles* sp: On *Coleophora fuscadinella*, in Sweden, 615. *Heptasmicra brasiliensis*; On *Oiceticus* (?) in S. Brazil, 714. *Heteroscapus ronnai*; On Larva of Unidentified Lepidopteron in S. Brazil, 714. Hymenoptera Parasitic on Injurious Insects in S. Brazil, 714. Hymenopterous Parasite, Unidentified: Cocoons found in Mines made by *Phloeosinus punctatus* in *Juniperus occidentalis*, 114. *Hyperrecteina polyphyllae*; On *Diatraea saccharalis*, in Brit. Guiana, 935. *Ipobracon grenadensis* and *I. saccharalis*; On *Diatraea saccharalis*, in Brit. Guiana, 935. *Itopectis maculator*; Of *Coleophora fuscadinella*, in Sweden, 615. Lice (Gen. *Haematopinus*); Of Field Mice in Italy, 1318. *Lyptopilus melano-*

*cephalus*: Of Undetermined Lepidopterous Larva, (*Cohns lesbia*?) injurious to Lucerne, in S. Brazil, 714. *Macrocentrus thoracicus*: Of *Olethreutes variegana*, in Italy, 611. *Masicera*: On *Gelechia ocellatella*, in Italy, 1315. *Metalaptus torquatus*; On Insects in Italy, 1059. *Metarrhizium Anisopliae*: On *Tomaspis saccharina*, in Grenada, 939. *Meteorus versicolor*; Of *Euproctis chrysorrhoea* imported into U. S. A. from Europe, 1433. *Microdus diatraeae*: On *Diatraea saccharalis*, in Brit. Guiana, 935. *M. mediator*: Of *Coleophora fuscedinella*, in Sweden, 615. *Microplitis alaskensis* and *Microplitis* sp.: Of *Autographa californica*, in Brit. Columbia, 1062. *Miotropis salicicrista*; Of *Coleophora fuscedinella* in Sweden, 615. Mites, Fam., *Gamasidae*; Of Field Mice in Italy, 1318. Mites; Of *Hylesinus vittatus* in Hérault, 602. *Monodontomerus aereus*: Of *Euproctis chrysorrhoea* in U. S. A., 1433. *Nectria* (?) sp.: Of *Aspidiotus* (*Chrysomphalus*) *aurantii*, 242. *Neomphaloidella ceroplastae*: Of *Ceroplastes galeatus*, 243. *Novius cardinalis*; Of *Icerya purchasi*, 244. *Omphalchrysocharis petiolatus*, reared from an Oscinid on a Daisy, at Washington D. C., 934. *Oniphilus caridei*: Of *Pulvinaria flavescens*; *P. minuta* and *P. platenensis*, in Argentina, 1308. *Opius concolor*: Of *Dacus oleae*, Acclimatisation Experiments in Italy, 1181. *Pachyneuron vindemmiae*: On *Lonchaea aristella*, in Italy, 716. *Pagasa fusca*: Of *Blissus leucopterus* in Illinois, 1431. *Pediculoides ventricosus*; Of *Acanthoscelides obtectus*, in Italy, 606. *Perezia legeri* on Larvae of *Pieris brassicae*, 603; and *P. mesnili*,

ditto, 370. *Pezomachus instabilis*, and *Phobocampa* sp.; Of *Coleophora fuscedinella*, in Sweden, 615. *Phora fasciata*; Of *Coccinella septempunctata*, 119. *Phorocera saundersi* Of *Autographa californica*, in Brit. Columbia, 1062. *Pimpla alternans*, Of *Clysia ambiguella* and *Pieris brassicae*, 366. *Pissidocystia oxycarenidis*: Of *Oxycarenus hyalinipennis* in Italian Somaliland, 1184. *Plagia americana*: Of *Autographa californica*, in Brit. Columbia, 1062. *Plecotus*: Gen. Bats, 1061. *Polycystus clypeatus*, reared from Leaf Miner on Maize in St. Vincent, 934. Protozoa (*Hepatozoon pitymysi*, *Hexamitus*, *Megastoma*, *Sarcocystis pitymysi*, *Trichomonas*): Of Field Mice, in Italy, 1318. *Pristomerus vulnerator*: Of *Olethreutes variegana* in Italy, 611. *Pseudaphelinus caridei*: On *Pulvinaria flavescens*, *P. minuta* and *P. platenensis* in Argentina, 1308. *Pseudomphale eudami*, reared from Larva of *Eudumis proteus*, in St. Vincent, 934. *Pteromalus caridei*; Of *Papilio thoantias*, in Argentina, 1065. *P. egyptius*, Ectoparasite: Of *Euproctis chrysorrhoea*, in U. S. A., 1433. *Reduviolus ferus* of *Blissus leucopterus* in Illinois, 1431. *Rhinolophus*; Gen. Bats, 1061. *Rhogas autographae*: Of *Autographa californica* in Brit. Columbia, 1062. *Salpingogaster nigra*; Of *Tomaspis saccharina*, in Trinidad, 939. *Sargatitis websteri*: Of *Autographa californica*, in Brit. Columbia, 1062. *Schedius kuwanae*: Of *Porthetria dispar*, in Spain, 1432. *Scleroderma domesticum*: Of *Phlaeotinus thuyae*, 366. *Scutellista cyanea*: Of *Ceroplastes galeatus*, 243. *Sinoxylon sexdentatum*: Of *Lonchaea aristella*, in Italy, 716. *Sporovella uvella*: of Larvae of *Eu-*

- noa excellens*, 494. *Stathmopoda oestethis*: of *Tachardia decorella*, 243. *Sycosoter lavagnei*: of *Hypoborus ficus*, 120. *Sylva hortensis*: of *Aphis laburni*, in S. E. Russia, 1180. *Synotus*: Gen. Bats, 1061. *Syntomaspis* (Gen): of *Rhynchites bacchus*, in Sicily, 374. *Tetrastichus caridei*: of *Pulvinaria flavescens*, *P. minuta* and *P. platanensis* in Argentine, 1308. *T. gowdeyi*: of *Pulvinaria jacksoni*, in Uganda, 243. *Thersilochus coeliodicola*: Of *Coeliodes ruber*, in Italy, 614. *Triphleps insidiosus*: of *Blissus leucopterus*, in Illinois, 1431. *Tyndarichus* n. sp. on Eggs of *Porthetria dispar*, in Spain, 1432. *Valvycystia rhopaloides*: Of *Oxycaenus hyalinipennis*, in Italian Somaliland, 1184. *Vespertilio*, *Vesperugo noctula*, *V. pipistrellus*, *V. serotinus*: Use of Bats in Control of Insects. Especially *Tortricidae* in Pine Woods, 1061. Worms, (*Gigantorhynchus moniliformis* (?) *Hymenolepis*, and *Oxyuris* (?); Of Field Mice in Italy, 1318. *Xiphidium fasciatum*: Of *Tomaspis saccharina* in Grenada, 939. *Xisticus lanio*: On *Coeliodes ruber*, in Italy, 614.
- Eniglaea apiata*, Cranberry Blossom Worm, 495.
- Ephestia elutella*: African Cacao resistant to attack, 519.
- Epiluchna punctipennis*: On *Aspidiotus destructor* in Uganda, 243.
- Epilobium montanum*: Immune Individual Plants to *Sphaerotheca Humuli*, 232.
- Epitetrastichus ugandensis*: On *Stictococcus gowdeyi* in Uganda, 243.
- Eragrostis*: *E. abessinica* and *E. curvula*: *Uromyces pedicellatus* in Transvaal, 1437. *C. cynosuroides*, Farm Weed in Sindh, (India), 484. *E. cynosuroides* and *E. pectinacea*: *Uromyces Eragrostis* in India and N. America, 1427.
- Eranthemum bicolor*: *Icerya seychellarum* in Uganda, 243. *Pulvinaria jacksoni* in Uganda, 242. *Eranthemum* sp.: *Icerya sulphurea* in Uganda, 242.
- Eremotes punctatulus*: On Ash in Hérault, 602.
- Erica Tetralix*: *Erigococcus devoniensis* in Great Britain, 485.
- Erinaceus europaeus*: In Sweden, 241.
- Eriobotrya japonica*: Lime Sulphur Spray against *Fusicladium pirinum* var. *Eriobotryae* in Italy, 599, 826.
- Errocampoides limacina*: On Cherry and Pear in Ontario, 247.
- Eriococcus*: *E. araucariae* in S. Africa, 244. *E. devoniensis*: On *Erica Tetralix* in Great Britain, 485.
- Eriogaster lanestris*: On Forest Trees in Sweden, 718.
- Eriophyes pyri*: On Pear in Ontario, 247.
- Eriosoma lanigera*: On Apple in Ontario, 247.
- Eriosphaeria Sacchari*: On Sugar Cane in Tropical and Sub-Tropical America, especially W. Indies, 1057.
- Eritrea: *Cecidomyidae*, On *Olea chrysophylla*, 945. Fungi, 477.
- Erysimum cheiranthoides* Host of *Myzus cerasi* in Ontario, 308.
- Erysiphe* sp.: On Cereals in Norway, 476. On Tobacco in Mauritius, 942. *E. Polygoni*: On Cultivated Cruciferae in U. S. A., 591. On Parsnips in England, 825.
- Erythrina excelsa*: *Aulacaspis chinensis*, 243, *Lecanium (Eulecanium) somereni*, 242. In Uganda.
- Erythroxylon Coca*: *Uredo Erythroxylonis* in Andes, 926
- Eublemma*: *E. costimacula*: On *Stictococcus diversiseta*, *E. scitula*: On *Inglisia conchiformis* in Uganda, 243.

- Eucalyptus* sp: *Aspidiotus* (*Chrysomphalus*) *rossi* in S. Africa, 242.
- Eudamus proteus*: *Grotiusomyia nigricans* and *Pseudomphale eudami* Reared from Larvae of *E. p.* at St. Vincent, 934.
- Eugenia*: *E. brasiliensis*; *Puccinia grumixamae* in Brazil, 586. *E. Jambolana*; *Asterina colliculosa* in the Philippines, 587, *Dialeurodes* (*Rustostigma*) *eugeniae* in India, 933. *E. malacensis* (Malacca Apple): *Lecanium* (*Eucalymnatus*) *tessellatum* and *L. wardi* in Brit. Guiana, 242. *E. micheli*: *Aleuroplatus* (*Aleuroplatus*) *cococolus*, in Brazil, 933. *E. operculata*: *Dialeurodes* (*Rachispora*) *trilobitoides* in Ceylon, 933. *Eugenia* spp.: *Pulvinaria platensis* in Argentine, 1308.
- Eulecanium*: *E. filamentosum* on Undetermined Plant and *E. somerem* on *Dolichandrone platycalyx*, *Morus* and *Tecoma stans*. in Uganda, 243.
- Eumicrosoma benefica*: On Eggs of *Blissus leucopterus* in Illinois, 1431.
- Eupelmus degeeri*: On *Rhynchites baccatus* in Sicily, 374.
- Euphorbia*: *E. hypericifolia*, Farm Weed in Sindh (India), 484. *E. Tirucalli*: *Phoma Baldratii*, 477. *Euphorbia* sp.: *Aphis* (?) in S. E. Russia, 1180.
- Euproctis chrysorrhoea*: Imported into U. S. A. from Europe: *Apanteles lacticolor*, *Meteorus versicolor*, obtained from Larvae of *Monodonotomerus aereus* and *Pteromalus egregius* (Ectoparasites), 1433.
- European Grain Aphid (*Aphis avenae*): On Apples, 247.
- Eurydema oleracea*: On Cabbage and Turnip, in Sweden, 241.
- Euscepes batatae*: On Sweet Potato, In W. Indies, 608, In Barbados, Jamaica, Hawaii, Norfolk Island, and Porto Rico, 936.
- Euthrips pyri*: On Fruit Trees in Norway, 476.
- Euxoa excellens*: On Vegetables in Brit. Columbia, 494.
- Evetria*: *E. buoliana* (Pine Shoot Tortrix Moth), 948, 1051. *E. (Retinia) resinella* and *E. turionana* (Pine Bud Tortrix), in France, 1061.
- Exoascus*: *E. Aceris*; On *Acer grandidentatum* in Utah, 103. *E. deformans*: 630; On Peach in Eritrea, 477.
- Exocentrus punctipennis*: On Elm and White Willow, in Hérault, 602.
- Exochomus 4-pustulatus*: Nat. Enemy of *Chrysomphalus dictyospermi*, 118.
- Exorista futilis*: On *Autographa californica* in Brit. Columbia, 1062.
- Eye Leaf Spot (*Helminthosporium Sacchari*): On Sugar Cane, 1057.
- "Ezer Jo" White Grapes resistant to Mildew (French Var), 105.
- "' agiuoli di S. Michele " ("F. pisani"): *Acanthoscelides obtectus*, 606.
- Fagus*: *F. laciniata* (= *F. sylvatica*) and *F. purpurea* Damage done by Tarring Streets of Milan (Italy), 584. *F. sylvatica*: *Pseudococcus newsteadii* in Great Britain, 485.
- Fall Army Worm (*Laphygma frugiperda*) 495.
- Fall Caulker-Worm (*Alsophila pometaria*), 247.
- Fall Web-Worm, (*Hyphantria cunea*), 247.
- False Chinch Bug (*Nysius ericae*), 1185.
- "Fattebarkborren" (*Dendroctonus micans*), 241.
- "Feinriesling": White Grape resistant to Mildew, 105.
- Fennec Fox: Destroyer of Injurious Animals and Insects, 1266.
- "Fernand Rose": White Grape, Var. Resistant to Mildew, 105.
- Ferns: In the Philippines: *Dialeuro-*

- des, (*Dialeuroplata*) *townsendi*, 933. In Uganda: *Alysius pterizoides*, 487, and *Saissetia hemisphaerica*, 243. "Ferrugem" (Rust) of Cacao, (*Phytophthora rubrocinctus*), 493.
- Festuca*: *F. elatior*: Danish Selection resistant to Rust (*Puccinia*), introduced into U. S. A., 138. *F. pratensis*: *Sclerotinia Trifoliorum*, 519. *Festuca* sp.: Observations on Damage done by Tarring Streets of Milan, Italy, 584.
- Field Mice, Diseases of: *Aspergillus*, *Penicillium* in Italy, 1318. *Bacillus* spp. Application, 1316. *Bacterium murisepticum*, Infection by, 1316. *Bacterium* spp. Infection by, 1316, 1318. Biological Control in Italy, 1316, 1317, 1318. Control by Acetylene Gas, 949. Eruption behind Ears - "Russa", 1318. Lice (*Haematopinus*) in Italy, 1318. On Mite of Fam. *Gamasidae*, Ectoparasite in Italy, 1318. *Pityomyia savii*, 1316, 1317, 1318. Protozoa (*Hepatozoon pityomyi*, *Hexamitus*, *Megastoma*, *Sarcocystis ritymyi*, *Trichomanas*) in Italy, 1318. Susceptibility to Certain Micro-organisms used to Control *F. m.* in Italy, 1317. Worms (*Gigantorhynchus moniliformis*? *Hymenolepis oxyuris*?) in Italy, 1318. Virus, Active (Preparation of.) and Method of Applying in Fields infested, 1316.
- "Fico a tre produzioni": Fig var attacked by *Lonchaea aristella*. in Italy, 716.
- Ficus*: *F. Carica*; *Ptychodes trilineatus* in America and Oceania, 248. *F. laurina*; *Idarnes carne* with *Blastophaga* sp.; and *Sycophila incerta* in Barbadoes, 934. *F. nota*; *Casca luzonica*; Endophagous Parasite of *Schizaspis lobata* in the Philippines, 1060. *F. rugosa*; *Aleuroplatus* (*Aleuroplatus*) *ficus-rugosae* in India, 933. *F. Sycomorus*; *Aphis ficus* in Egypt and Uganda, 487. *F. Thonningii*; *Ceroplastes ceriferus*, *C. ficus* and *C. galeatus*, *Ceroplastodes gowdeyi*, *Selenaspidus articulatus*, and *Tachardia longisetosa* in Uganda, 243. *Ficus* sp.; *Aleuroplatus* (*Aleuroplatus*) *oculiminatus* in Trinidad 933. *Aspidiotus articulatus* and *A. palmarum* in São Thomé, 609. *A. (Chrysomphalus) ficus* in S India, 242. *Ceroplastes conformis* in Uganda, 243. *Dialeurodes* (*Gigaleurodes*) *maxima* in the Philippines, 933. *Ischnaspis filiformis* in Jamaica, 242. *Lecanium* sp. in São Thomé, 609. *Pulvinaria cupaniae* in Jamaica, 242. *Saissetia nigra*, 243, and *Stictococcus formicarius* in Uganda, 242, 243. *Trabutia chinense* in S China, 350.
- Fig: *Aspidiotus camelliae* in Brit. E. Africa, and *A. cydoniae* in Coimbatore, 242. *Ceratocarpia Cactorum* with *Ceroplastes rusci* in France, 821. *C. rusci* on Fig attacked by *Chilocorus bipustulatus* in Algeria, 828. *Choerorhinus squalidus* in Hérault, 602. *Lonchaea aristella* in Italy, 716. Locusts in Capitanata (Italy), 1311. *Ptychodes trilineatus*, Three-Lined Fig-Tree Borer, on *Ficus Carica*, 248. *Scobicia chovrieri* in Hérault, 602. *Sycosoter lavagnei*; On *Hypobornus ficus* in France, 120. Wild Fig: In Italy; *Lonchaea aristella*, 219, 716, and *Oscinosoma discretum*, 249.
- Fiji: *Aleyrodidae*, 933. Coccidae, 242.
- "Finger and Toe" (*Plasmodiophora Brassicae*), 594.
- Florina*: *F. florinae*: On Undetermined Plant from Madeira, Attacked by *Aspidiotophagus lounsburyi*, 118; In S. Africa, 244. *F. proboscidea*; On Citrus imported from India, to Jamaica, 244.

- Firmiana platanifolia* (= *Sterculia platanifolia*): *Helicobasidium Tanaka* in Japan, 705.
- "Fiskmåsen" (*Larus canus*), 241.
- "Fjaderborstflyet" (*Dasypolia templa*), 241.
- "Fjällemeln" (*Lemmus lemmus*), 241.
- Flat-headed Apple Tree Borer. (*Chrysobothris femorata*), 496.
- Flax: *Colletotrichum* Linn, U. S. A. (Flax Canker); *Coll. sp.* in Holland; "Yellowing" in Ireland, 1305. *Colletotrichum lincolnum*, n. sp. on Seedlings, in Ireland, also from Seed from Russia, Holland, Canada and U. S. A., 1305. Flaxwilt (*Fusarium* Linn): Study of Nature and Inheritance of wil Resistance, 283.
- "Flax Canker" (*Colletotrichum Lini*), 1305.
- Florida: *Aecidium Gossypii*, Cotton Rust, 479. *Aleyrodidae*, 933. *Bacillus Solanacearum*; On *Ricinus*, 1055. *Clytus devastator*; On *Citrus*, spp. etc., 1437. *Hoplia floridana*; On *Citrus* spp. etc. 946. *Ptychodes trilineatus*; On Fig, 248. *Sclerotinia Libertiana*; On Lettuce, 583. *Tylenchus penetrans*; On Camphor, 491.

- Glochidion obovatum*: *Septobasidium Acaciae* in Japan, 705.
- Glocosporium*: *Gl. Ailanthi*; On *Ailanthus glandulosa* in Louisiana, 103. *Gl. Bartholomaei*; On *Ribes bracteosum* in State of Washington, 103. *Gl. Betae*; On Sugar Beet in Montana, 103. *Gl. Crataegi*; On *Crataegus brevissima* in Washington State, 103.
- Glypta* sp.: Nat. Enemy of *Coleophora fuscadinella* in Sweden, 615.
- Gnathotrichus*: In Oregon: *G. retusus*; On *Pinus contorta*, *P. ponderosa*, *Pseudotsuga taxifolia* and *Tsuga heterophylla*. *G. sulcatus*; On *Abies grandis*, *A. nobilis*, *Pseudotsuga taxifolia* and *Tsuga heterophylla*. *Gnathotrichus* sp.: On *Acer macrophyllum* and *Alnus oregana*, 114.
- Gnomonia Iliac*: On Sugar Cane in Tropical, Sub-Tropical America, especially W. Indies, 1057.

- Gold Coast : *Cercospora latimaculans* ;  
On *Bauhinia*, 1295. Coccidae, 242.  
*Physothrips marshalli* ; On Potato,  
etc., 937.
- Golden Hop : Form of *Humulus Lupulus* with Yellow Leaves, immune to  
Hop Mildew (*Sphaerotheca Humuli*).  
in England, 232.
- "Goldriesling" White Grape Var.  
Resistant to Mildew, 105.
- Gonocephalum hoffmannseggii* : On Stored  
Food Stuff in Java, 1438.
- Gooseberry : Vars Resistant to *Puccinia Ribis* in U. S. A., 519 *Pristiphora appendiculata* and *Pterodinea* (*Pteronius*) *ribesii* in Sweden,  
241. *Sphaerotheca mors-uvae* in Norway,  
476.
- "Gorgojo de la batata" "G. de la  
raiz de la batata" (*Cylas formicarius*), 1434.
- Gossyparia ulmi* : On *Ulmus campestris* var. *cornubiensis* and *U. Dampieri* var. *aurea* in England,  
485.
- "Gougenot" : Red Grape Var. Resistant  
to Mildew, 105.
- Gourd : *Autographa californica*. in U.  
S. A., 1062.
- "Grass (Grass)" (*Paspalum* sp.) : *Scapteriscus vicinus* in Porto Rico, 1063.
- Gramineae : *Apamea testacea* in Sweden,  
241. *Ripensia halophila* in Great Britain,  
485. Field Grasses : Damage done by Tarring Streets of Milan, (Italy), 584. Fodder Gr. : *Amaurosoma* (*Cleigastrea*) *armillatum* and *A. flavipes* ; On *Phleum*, in Sweden, 241.
- "Granbarkbörren" (*Ips typographus*),  
718.
- Great Britain : *Acanthoscelides obtectus*, 606. *Actinonema Rosae*, Rose  
Blotch Fungus ; Life History, 1296 *Bacillus atrocephalus*, Cause of "Blackleg"  
in Potato in Lancashire, 358. *Chrysomya Abietis* ; On  
Spruce, 363. Coccidae, 485. Diseases  
of Parsnips, 825. Fungi,  
1424. Hop (Forms of) resistant  
to Mildew, (*Sphaerotheca Humuli*),  
232. *Pseudomonas seminum* ; On  
Peas, 595. *Sphinx convoluti* in  
1917, 115 *Stephanitis rhododendri* ; On Rhododendrons, 941.
- "Granknoppsmalen" (*Argyresthia illuminatella*), 718.
- Grapes see Vine.
- "Grapevine Aphid" (*Macrosiphum illinoensis*), 367.
- Graphiola Phoenixis* : On *Phoenix* sp.,  
*Ph. abyssinica* and *Ph. dactylifera*  
in Eritrea, 477.
- Grapholitha nigricana* : On Leguminosae,  
in Sweden, 241.
- "Gråsparven", (*Passer domesticus*),  
241.
- Greece : *Aphelinus chrysomphali*, Nat.  
Enemy of *Aonidiella auranthi* on  
*Cedrus* sp., (Lemons and Cedrates),  
118. Control of Field Mice by  
Acetylene Gas, 949.
- Green Fruit Worms : (*Xylina*, spp.),  
247.
- Green Soldier Bug, (*Nezara viridula*),  
927.
- Grenada : *Paleopus grenadensis*, 608.  
*Tomaspsis saccharina* ; On Sugar  
Cane, and its Nat. Enemies, 939.
- Grevillea : *Pseudococcus flamentosus*  
in S Africa, 244.
- Grey-back Cockchafer, (*Lepidota albolineata*), 246.
- Grindelia squarrosa* : Amongst Cereals  
in Montana, 639. *Cinnabolum majus*  
and *Oidium* sp. in Montana  
U. S. A., 103.
- Gros Pinot blanc hâtif, Var. (Vine)  
Resistant to Mildew, 105.
- Grossularia : *G. meritis* : *Coleosporium rubicola* in New Mexico, 585.  
In Arizona and Colorado : *G. inermis*,  
*G. leptanthes*, *G. missouriensis* and *G. reclinata* × *G. hirtella*  
attacked by *Cronartium occidentale*,  
1428.

- Grotiusomya*: *G. flavicornis* reared from a Pyralid Leaf Minor on Oak, U. S. A., 934. *G. nigricans* reared from a Larva of *Eudamus proteus* in W. Indies, 934.
- Ground Rot (*Sclerotium Rolfsii*): Of Water Melon, 238.
- Gryllidae: On *Oxycoccus macrocarpus*, in U. S. A., 495.
- Gryllotalpa gryllotalpa* in Sweden, 241.
- Guam: *Euscepes batatae*; On Sweet Potato, 936.
- Guatemala: *Acanthoscelides obtectus*, 606. *Cylas turcipennis*; On Sweet Potato, 936. *Ptychodes trilineatus*; On Fig, 248.
- Guava, (*Psidium Guajava*): In Belgian Congo; *Chamus tuberculatus*, 940. In Brazil, *Aleurothrixus (Aleurothrixus) floccosus* and *A. (A.) howardi*, 933. In Cuba, *Aleurocanthus woglumi*, 1186. In S. India, *Pulvinaria psidii*, 242. In Uganda, *Aspidiotus cyanophylli*, 242. *As. cydoniae*, 242, 243. *As. destructor*, 242, 243. *Ceroplastes destructor*, *C. singularis*, *C. vinsonoides*, 243, *Coccus setiger*, *C. signatus*, *C. viridis*, 243. *Icerya sulphurea*, 243. *Inglisia conchiformis*, 243. *Pulvinaria psidii*, 243. *Tachardia decorella*, *T. longisetosa*, 243.
- Guiana, British: *Aleyrodidae*, 933. *Coccidae*, 242. Diseases of Sugar Cane, 1057. *Ipobracon grenadensis*, *I. saccharatus* and *Microdus diatraeae* on *Diatraea saccharalis*; On Sugar Cane, 935.
- Guiana, Dutch: Diseases and Injurious Insects; On Citrus, 300. *Hevea brasiliensis* Leaf Disease (*Scolecotrichum* sp.), 236.
- Gulhåriga skinnarbaggen " (*Blitophaga [Oiceoptoma] opaca*), 241.
- Gurming: Sugar Cane, (*Bacterium vascularum*), 1057.
- Gummosis; On Citrus sp. in Surinam, Dutch, Guiana, 300. *M.*

- "Gurukina" (*Calophyllum Burmanni*), 109.
- Gymnaspsis africana*: On Undertermined Plant, in Uganda, 243.
- HABROCYTUS RADIALIS* Nat: Enemy of *Coleophora fuscudinella* in Sweden, 615.
- Hadronema orbiculare*: On *Quercus* sp. in the Philippines 587.
- Haematopinus*; On Field Mice in Italy, 1318.
- "Hallonviveln" (*Anthonomus rubi*), 241.
- Haronga madagascariensis*: *Inglisia conchiformis* and *Stictococcus gowdeyi* in Uganda, 243.
- Harpulla*: *H. pendula* attacked by *Aleurobus setigerus*, and *Harpullia* sp. by *Dialeurodes (Rachisphora) trilobitoides*, In Ceylon, 933.
- "Havrebladlusen" (*Aphis avenae*), 476.
- Hawai: *Cylas formicarius* var. *elephantulus* and *Euscepes batatae*; On Sweet Potato, 936. Mite Disease of Potato, 1314.
- Haworthia margaritifera*: Observations on Damage done by Tarring Streets of Milan (Italy), 584.
- Hazel: *Sciurus vulgaris* in Sweden, 241. Observations on *Coeliodes ruber*, injurious Coleopteron, and on *Balaninus nucum* (Nut Weevil) in Italy, 614.
- Helianthus* spp.: *Autographia californica*: in U. S. A., 1062. *Physothrips hellyanus* in N. Queensland (?), 937. *H. annus*: Harmful Weed amongst Cereals in Montana, U. S. A., 639.
- Helicobasidium*: *H. longisporum*; On *Theobroma Cacao* in Uganda, 228. *H. Tanakae*; On *Firmiana platanifolia* (= *Sterculia platanifolia*), *Juglans* sp., *Kerria japonica*, *Mo-*

- rus* sp., *Paulownia tomentosa*, *Pittosporum undulatum*, *Prunus Armeniaca* var. *Ansu*, *P. donarium* (= *P. paniculata*), *P. Mume*, *P. salicina*, *Pyrus Malus*, *P. sinensis*, *Ribes* sp., *Grossularia* sp., *Salix* sp., *Thea sinensis*, *Vitis* sp., *Zanthoxylum* in Japan, 705.
- Heliconia*: *Aleuroplatus* (*Aleuroplatus*) *sculpturatus* in Panama, 933.
- Heliothis armigera*: On Tobacco in Mauritius, 942.
- Helminthosporium*: 593. *H. geniculatum* and *H. gramineum* (?) On Wheat in Java, 1426. *H. Manihotis*; On *Manihot Aypi* in Brazil, 586. *H. Ravenelii*; On *Sporobolus elongatus* in S. China, 350. *H. Sacchari*: On Sugar Cane in Tropical, Sub-Tropical America, Especially W. Indies, 1057. *H. Warpuriae*; On *Warpuria clandestina* in Great Britain, 1424.
- Helopeltis antonii*, 493.
- Hemerobius*: On *Blissus leucopterus* in Illinois, 1431.
- Hemerocampa leucostigma*: On Apple, Pear, and Plum in Ontario, 247.
- Hemiberlesia camelliae*: On Robinia, Host of *Signiphora merceti* in Italy, 118.
- Hemichionaspis*: *H. aspidistrae* and *H. minor*, Attacked by *Aspidiotiphagus citrinus*, in Italy, 118. *H. chionaspiformis*: On Undetermined Plant in Uganda, 243.
- Hemidesmus indicus* ("iramusu"); Attacked by *Hypochnus* sp. in Ceylon, 109.
- Hemilecanium imbricans*; On *Cedrela Toona*, in S. Mysore, 242.
- Hemilera vastatrix*: Resistant Hybrid vars. of Coffee in E. Indies, 519.
- Hemiteles* sp.: Nat. Enemy of *Coleophora fuscidenella* in Sweden, 615.
- "Hemlock Tree" (*Tsuga canadensis*), Disease of, 110.
- Hemp: *Cercospora cannabina* in Uganda, 228. Mildew (*Peronospora cannabina*) in Italy, 107.
- Hepatozoon pitymysi*: On Field Mice in Italy, 1318.
- Heplasmicra brasiliensis*: Possible Parasite of *Onceticus*, in S. Brazil, 714.
- Heracleum Sphondylium*: *Phyllachora Heraclei* in England, 825.
- "Herba pega pega" (*Megaclinium falcatum*), in São Thomé, 609.
- Herpestes*: In Grenada, 939.
- Heterocordylus malinus*: On Apple in Ontario, 247.
- Heterodera*: *H. radicola*: On Water Melon, in U. S. A., 238. On Cultivated Cruciferae in U. S. A., 594. Iron Var. *Vigna Catjang* and Crosses with Black and Whippoorwill Resistant Vars, in U. S. A., 519.
- H. schachtii*: Series of Trials to obtain a type of resistant sugar Beet in Germany, 519. *Heterodera* sp.: On Tobacco in Mauritius, 942.
- Heteroscapus romnai*: On Larva of Unidentified Lepidopteron, 714.
- Hevea brasiliensis*: In Federated Malay states: *Fomes pseudo-ferreus*, 1295; *Hymenochaete noxia* (Brown Root Disease) and Danger of burying Felled Coconut Trees between Rows of Rubber Trees, 1056, *Poria hypolateritia*, 1056, 1295. In Singapore: *Xylaria* (*Xyloglossa*) *obovata*, *Xyl.* (*Xylogl.*) *scapiformis* var. *heveana*, *Xyl.* (*Xylogl.*) *tuberculiformis*, 1173. In Trinidad, Surinam and Demerara: S. American *Hevea* Leaf Disease, (*Scolecotrichum* sp.), 236. In Uganda: *Aspidiotus destructor*, 242.
- Hexagonia subvelutina*: On Wood in E. Africa Protectorate, 228.
- Hexamitus*: On Field Mice in Italy, 1318.
- Hibernia defoliaria*: On Forest Trees in Sweden, 718.

- Hibiscus* sp.: *Ceroplastes ceriferus*, *Inglisia conchiformis* and *Stictococcus diversiseti* in Uganda, 243. *H. sinensis*: *Phytothrips marshalli* on Gold Coast, 937.
- Hickory (Oak) Cossid (*Cossula magnifica*), Hickory Phylloxera (*Phylloxera caryaecaulis*) Hickory Twig-Girdler (*Oncideres cingulatus*), 496.
- Himantia stellifera*: On Sugar Cane in Tropical, Sub-Tropical America, especially the W. Indies, 1057.
- Hoheria populnea* (Lacebark): *Puccinia Hoheriae* in N. Zealand, 228.
- Holland: *Colletotrichum* spp on Flax, 1305. *Stephanitis rhododendri* on Rhododendrons, 944.
- Homalotylus flaminus*: On *Chilocorus bipustulatus*, Nat. Enemy of *Chrysomphalus dictyospermi*, 118.
- Homoeosoma nebulella*: Resistant Hybrid vars of Sunflower in Russia, 519.
- Honduras, British: *Ptychodes trilineatus* (Three-Lined Fig Tree Borer), 248.
- Hoplia floridana*: On Citrus in Florida, 946.
- Hoplocampa minuta*: On Plums in Sweden, 241.
- Hops (*Humulus Lupulus*): Forms of Hops resistant to Mildew *Sphaerotheca Humuli* and *H. Lupulus* var. *cordifolius* subject to attack, In England, 232.
- Hordeum*: *H. distichon* and *H. hexastichon*: *Bacterium translucens* in U. S. A. (?) 593. *Hordeum* sp; *Septoria graminum* and *Ustilago Hordei* in Eritrea, 477. *H. trifurcatum*: *Ustilago Hordei* in New Mexico, 585. *H. vulgare*: *Bact. translucens* in U. S. A. (?), 593; Damage done by Tarring Streets of Milan, (Italy), 584.
- Hormomyia oleiphila*: On *Olea chrysophylla* in Eritrea, 945.
- Howardia biclavis* and *H. moorsi*: In S. Africa, 244.
- Hura crepitans*: *Ceroplastes conformis* in Uganda, 243. *C. cirripediformis* and *Lecanium (Akeres)* sp. in British Guiana, 242.
- "Hvittraate" (*Pseudomonas destructans*), on Carrots, 476.
- Hyalopterus*, *Hyal. insignis*; on *Arundo*: *Hyal. pruni* (*Hyal. arundinis*, *Hyal. phragmiticola*); On *Prunus*, *Arundo* and Apricot in Egypt, and on Apricot in England, 487.
- Hybrid Bearers: Resistance to Disease in France, 330, 770.
- Hydrangea*: Damage done by Tarring Streets of Milan (Italy), 584.
- Hydrellia griseola*: On Oats in Norway, 476.
- Hylastinus obscurus* (Clover Root Borer). In Oregon, 114. *Hylemyia coarctata*: On Cereals in Sweden, 241.
- Hylesinus*: In Oregon: *H. aculeatus*, On *Fraxinus oregana*, *H. aspericollis*; On *Alnus oregana*, *H. dentatus*; On *Juniperus occidentalis*, *H. granulatus*; On *Abies grandis*, *H. imperialis* (rare), 114. In Hérault (France): *H. vittatus*; On Young Elm and on *Rhamnus Alaternus*, 602.
- Hylobius abietis*: On Forest Trees in Sweden, 718.
- Hylurgops* spp: In Oregon: *H. lecontei*; On *Pinus contorta* and *P. ponderosa*, *H. rugipennis*; On *Pinus monticola*, *H. subcostulatus*; On *Pinus ponderosa*, 114.
- Hymenolepis*: On Field Mice in Italy, 1318.
- Hymenoptera: Parasitic on Injurious Insects in S. Brazil, 714. Unidentified Parasite in Mines made by *Phloeosinus punctatus* in *Juniperus* sp. in Oregon, 114.
- Hyperectema*: *Hyp. metopina*, 371; *Hyp. polyphyllae*; On *Polyphylla fullo* in Russia, 371.

- Hyphantria cunea* (Fall Webworm): On Apple and Pear in Ontario, 247. On Peanut in U. S. A., 496.
- Hypoborus ficus*; Parasitised by *Sycosoter lavagnei*, in France, 120.
- Hypochnus Sacchari*: On Sugar Cane in Tropical, Sub-Tropical America, especially in the W. Indies, 1057.
- Hypochnus* sp.; On Tea in Ceylon, 109.
- Hypochoeris radicata*: *Physothrips kellyanus* in Victoria (Australia), 937.
- Hyponomeuta malinellus*: On Fruit Trees in Sweden, 241.
- Hypothenemus ritchiei*: On Dried Sweet Potatoes in Jamaica, 607.
- Hystrichopsylla*: On Field mice in Italy, 1318.
- ICERYA: *I. aegyptiaca*: On Date Palm in Zanzibar, 242. *I. caudata*; On *Codiaeum*, in Uganda, 243. *I. maxima*; On Tree Trunk, Uganda, 242. *I. nigrareolata*; On Coffee and *Codiaeum* in Uganda, 243. *I. purchasi* in S. Africa, 244, and On *Acacia dealbata*, *A. decurrens* and *Casuarina* in Ceylon, 245. *I. seychellarum* in S. Africa, 244. In Uganda: On *Eranthemum bicolor*, and *Monodora Myristica*, 243. On Mango, 242, 243. *I. sulphurea*; On *Castilloa* (?) and *Eranthemum*, 242. On *Castilloa* Rubber and Guava (*Psidium Guajava*), 243.
- Idaho (U. S. A.): *Autographa californica*, 1062.
- Idarnes carme*: Reared with a *Blasiphaga* from *Ficus Caurina* in Barbados.
- Ilex*: *Ilex integra*: *Dialeurodes (Rusostigma) tokyonis* in Japan, 933. *Ilex* sp: (*Aleuroplatus*) *Aleuroplatus berbericohus* in Mexico, 933. *Autographa californica* in Brit. Columbia, 1062.
- "*Iliax*" (Stem Rot) of Sugar Cane (*Gnomonia Iliax*), 1057.
- Illinois: *Aleyrodidae*, 933. Enemies of Chinch-Bug (*Blissus leucopterus*), 1431. *Macrosiphum illinoensis*, (Grapevine Aphis, 367).
- "*Illuc*" (*Imperata arundinacea*), 1123.
- Immunity of Plants to Principles formed by them, 1006.
- Imperata*: *I. arundinacea*: *Leucaena glauca* used to exterminate *I. a.* in the Philippines, 1123. *I. exaltata* (Cogon Grass): Favourable to Locust Breeding in the Philippines, 53. *Imperata* spp.; *Aleurocybotus setiferus* in Java, 933.
- Insects, Injurious. On Cocoa-tree in State of Bahia, (Brazil), 493. On Citrus in Dutch Guiana, 300. On Cultivated Plants in Norway, 1916, 476. On Cultivated Plants in Sweden, 1912-1916, 241. On Forest Trees in Sweden, 1916, 718. On Fruit Trees, in Ontario, 247. On Lucerne in Oasis of Tripoli, 235. On Onions in Indiana, 422. On *Oxycoctus macrocarpus*, in U. S. A., 495. On Pecan, in U. S. A., 496. On Rice in the British Empire, 254. On Sorghum in Kansas (U. S. A.), 760. Pests of Stored Food Stuff, in Java, 1438. On Sweet Potato in Philippines, 864. On Tobacco from Réunion grown in Mauritius, 942. On Watermelon in U. S. A., 238.
- India: *Aleyrodidae*, 933. *Cercospora personata*; On *Arachis hypogaea*, 350. Coccidae, S. India, 242. *Cosmopteryx bambusae*; On Bamboo, and *C. phaeogastra*; On Bean, at Pusa, 372. *Cylus turcipennis*, On Sweet Potato, 936. Farm weeds in Sindh, 484. Fungi, 1295. Fungus Unidentified; On *Cedrus Deodara* in Bashar Division, 483. *Lepidocoris varicornis*; On Rice in Assam, 604. *Physothrips lefroyi* and *Phs. setiventris*; On Tea, 941. *Pseudomonas Tritici*; On Wheat in

- Punjab, 592. Resistant Wheat Vars. to Rust, to *Tilletia levis* and *T. tritici*, 519. Selected Resistant Vars. of Wheat, against Rust and Lodging, 854. "Spike" Disease of *Santalum album* in Mysore, 5. Smuts on Sorghum in Bombay Pres., 1054. *Uromyces Eragrostidis*; On *Eragrostis cynosuroides*, 1427.
- Indiana: Insect Pests and Diseases of Onions, 422. *Macrosiphon illinoisensis* (Grapevine Aphis), 367. *Phthorimaea operculella*; On Potatoes, 1183.
- Indigofera: attacked by *Ceroplastodes cajani* in S. India, 242.
- Indo-China: Plant Diseases, 1068.
- Inglesia: *I. castilloae* var. *theobromae*; On Cacao in Uganda, 243. *I. chelonoides*; On *Parkinsonia aculeata* in Coimbatore, 242. *I. conchiformis*: On *Gliricidia maculata* on Gold Coast, 242.
- Ink Disease of Chestnut (*Blepharospora cambivora*), 361, 1050.
- Ipobracon grenadensis* and *I. saccharalis*: On *Diatraea saccharalis* in Brit. Guiana, 935.
- Ipomoea*: *I. Batatas*: Weevils injurious to Sweet Potatoes, 936. *I. Bona-nox*: *Physothrips marshalli* on the Gold Coast., 927. *Ipomoea* sp. Host of *Ceroplastes cirripediformis* associated with *Lecanium (Akermes)* sp. in Brit. Guiana, 242.
- Ips*: In Oregon: *I. caelatus* var; On *Picea Engelmanni*; *I. concinnus*; On *Picea sitchensis*, *Pinus contorta* and *Pseudotsuga taxifolia*; *I. confusus*; On *Pinus* sp, *I. emarginatus*; On *Pinus contorta* and *P. ponderosa*, *I. interpunctatus*; On *Pinus contorta*, *I. interruptus*; On *Picea sitchensis*; *I. latidens* and *I. oregona*; On *Pinus ponderosa*; *I. pini*; *I. radiata*; On *P. contorta* and *P. ponderosa*; *I. rectus*; and *Ips* n. sp.: On *P. ponderosa*. 114.
- In Sweden: *I. acuminatus*, *I. sex-dentalis*, and *I. typographus*; On Forest Trees, 718; *Ips* sp.; On Forest Trees, 241.
- "Iramusu" (*Hemidesmus indicus*), 109.
- Ireland: *Bacillus melanogenes*, Cause of Blackleg in Potato, 358. *Colletotrichum linicolum* on Flax, 1305. Tobacco Vars. Broad Leaf Burley and Irish Gold, susceptible to Root Rot caused by *Thielavia basicola*, (1916), 49.
- Iris: *I. florentina*, *I. foetidissima*, *I. germanica* and *I. Pseudacorus*: *Mononychus punctum-album* in Hé-rault, 602.
- Irish Gold, Variety of Tobacco liable to Root Rot (*Thielavia basicola*) in Ireland in 1916, 49.
- Iron Variety of *Vigna Catjang* resistant to *Fusarium tracheiphilum* and *Heterodera radiculicola* in U. S. A., 519.
- Ischnaspis*: *I. filiformis*; On *Ficus* in Jamaica and on Coffee in Uganda, 242. *I. longirostris*; On Bamboo, Coffee and Palms in Uganda, 243; On *Citrus* and Ornamental Plants in S. Africa, 244.
- "Isoca de los naranjos" (*Papilio thoantiades*), on Citrus, 1065.
- Issatschenko, Bacillus of, 1316.
- Italy: *Aleyrodidae*, 933, Bacteria and Fungi recorded as Parasitic on Cultivated Plants in Prov. of Turin and Adjacent Regions, 1916, including Bacteriosis of Dwarf Bean and Peach, and their Use, 925. *Bacterium murisepticum*, Specific Agent of an Infections Disease of Field Mice (*Pitymys savi*) in Apulia, 1187. *Balaninus nucum*, Nut weevil, 614. *Blepharospora cambivora* n. gen. and. n. sp. Cause of "Ink Disease" of Chestnut Trees, 361. Cecidomyd Flies living on *Olea europaea*, 945. Ce-

real Mildew (*Sclerospora macrospora*) on Maize in Piedmont, 1053. Chas-selas × Berlandi 41 B. Vine, Resistant to Bramble-leaf Disease, in Sicily, 873. *Coeliodes ruber*, Coleopteron injurious to Hazel Trees, 614. Copper Sulphate, Production and Consumption, 1210. Deformities caused by Animals on Fruit Trees in Sicily, the Most Common vars, 610. Disinfection of Dwarf Beans infested with *Acanthoscelides obiectus* and *Spermophagus subfasciatus*, 605. Elm and Nettle tree (*Celtis australis*), Diseases of, in Aquila, 1293. Field Mice, Biological Control of, 1316, 1317, 1318. Fungi from the Campania, 1173. Fungi of the Valley of San Martino or the Valley of Germanasca, Piedmont, 1294. *Fusicladium pavinum* var *Eriobotryae* on Japanese Medlar Tree in Sicily; Treatment with Lime-Sulphur Mixture, 599. *Gelechia ocellatella* on Beet in Tuscany, 1315. Grafting Stock in Sicily: Resistance to Chlorosis of Stock imported from France, 651. Hop (*Humulus Lupulus*) Forms of, Resistant to Mildew (*Sphaerotheca Humuli*) in England, raised from Seed from Hop found Wild at Vittorio (Treviso), 232. Hop Mildew, (*Peronosplasmopara cannabina*), Observations on, 107. Locusts, Control of, in Capitanata in 1917, 1311. Locusts, Control Orders, 1918, 1291. *Lonchaea aristella*; On Fig and Wild Figs, 249, 716. *Megastigmus balleslevieri* (= *Trogocarpus balleslevieri*); On Pistachio and Turpentine Trees in Sicily, 831. *Metalaptus torquatus*, Chalcid, in Sicily, 1059. *Monilia* sp. Cause of Specific Gummosis of Apricot, in Emilia, 1598. Myxomycetes and Fungi of Prov. of Verona, 1172. Nat. Enemies of *Chrysomphalus*-

*dictyospermi*, Coccid Injurious to Citrus, 118. Observations on *Acanthoscelides obiectus* (Bean Weevil), including Attacks on *Dolichos melanophthalmus*, *Vicia Faba*, *Lupinus albus*, *Lathyrus sativus*, *Pisum sativum*, and Maize; Nat. Enemy, *Pediculoides ventricosus*, 606. *Olethreutes variegana*, on Fruit Trees, Description, Morphological and Biological, 611. "Olive Fly" (*Opius concolor*) African Hymenopteron, Acclimatisation Experiments, 1181. *Oscinosoma discretum* on Fruit of Wild Figs, Prov. of Naples, 249. *Phyllosticta Rabiei*, Deuteromycete, Specific Agent of "Rabbia" or Anthracnosis of Chick Pea, 1177. *Rhynchites bacchus*, (parasitised by *Eupelmus degeeri* *Syntomaspis* sp.) *Rhyn. auratus*, *Rhyn. giganteus* and *Rhyn. ruber*, Injurious Coleoptera to Apples, Apricots and Plums in Sicily. Service of "Preventive Detection" against Vine Mildew, founded by the Phytopathological Observatory of Turin, 925. Tarring Streets of Milan, Damage done to Trees and Plants, 584. Transplanting in the Control of "Wild" Rice ("Riso crodo" or "riso selvatico"), 161. "Verde secco" (*Rosellinia necatrix*) of Fruit Trees in Apulia, 597.

*Itopectis maculator*: Nat. Enemy of *Coleophora fuscedinella* in Sweden, 615.

*Iva xanthifolia* (Marsh Elder): Amongst Cereals in Montana, U. S. A., 639.

JAMAICA. *Aleyrodidae*, 933. *Aschersonia* sp.; On *Aleurocanthus woglumi*, 1186. Coccidae, 242. *Euscepes batatae*; On Sweet Potato, 936. *Hypothenemus ritchiei*, n. sp. Scolytid; On Dried Sweet Potatoes, 607. *Palaeopus costicollis*, New Weevil Pests; On Sweet Potatoes,

608. *Pal. dioscoreae* on Yams, 936. Sugar Cane, Diseases of, 1057
- Japan : *Aleyrodidae*, 933. New Fungi 102, 705.
- "Japansche luis" (*Stephanitis rhododendri*), 944.
- Jasminum* : *Dialeurodes* (*Dialeurodes*) *kirkaldyi*, in Brit. Guiana, 933.
- Jatropha Curcas* : *Chionaspis* (*Hemichionaspis*) *minor* and *Pseudococcus virgatus*, on Gold Coast, 242.
- Java : *Aleyrodidae*, 933. *Cylas turcipennis*; On Sweet Potato, 936. Diseases reported, on Wheat (*Gibberella Saubinetii* (= *Fusarium rostratum*), *Helminthosporium geniculatum*, *H. graminum*, *Nigrospora Panici* and *Ustilago Tritici*), 1426. Pests of Stored Food Stuffs, 1438. *Septogloeum Arachidis*; On Peanuts, 350.
- "Johnson Grass" (*Sorghum halepense*) Weed in Porto Rico, 1430.
- Jonathan-Spot of Apples, 1048.
- "Jordbaermidde" (*Tarsonemus fragariae*), 476.
- "Jordlopporma" (*Phyllotreta* sp.), 241.
- "Jowar" (Cultivated Vars. of *Andropogon Sorghum* = *Sorghum vulgare*) in Bombay Pres., 1054.
- Juglans* : *Helicobasidium Tanakae* in Japan, 705.
- Juniperus occidentalis* : *Hylesinus dentatus* and *Phloeinus punctatus*, in Oregon, 114.
- "KAALSTANKELBENET" (*Tipula olivacea*), 476.
- "Kabab" (*Cyperus rotundus*), 484.
- Kafir Ants : In Kansas, 760.
- "Kajan" (*Corvus monedula*), 241.
- "Kalati"; *Aspidoproctus pertinax*, 242.
- "Kålflugan" (*Chorthippa* [*Phorbia*], *brassicae*), 241.
- "Kålmalen" (*Plutella maculipennis*), 241.
- Kamerun : *Cylas femoralis*; On Sweet Potato, 936.
- Kansas : *Cronartium occidentale*; On *Ribes aureum*, 1428. *Nysius ericae* (False Chinch Bug); On Sugar Beets and Cruciferous Garden Crops, 1185. Sorghum; Attacked by Kernel Disease, Chinch Bugs, Grasshoppers and Kafir Ants, 760.
- Kashaku "Ko-maruboshiyô", (*Mycosphaerella Harii*), and "Kasshoku Ô-maruboshiyô" (*Phyllosticta citricola*); (Japanese Fungi), On Citron, 102.
- Keithia Chamaecyparissi*: On *Chamaecyparis thyoides*, in New Jersey, 1307.
- Kennedya rubicunda*: Leguminous Plant injurious to Forest Trees, in New South Wales, 239.
- Kentia* sp.: Damage done by Tarring Streets of Milan, (Italy), 584. *Pseudococcus nipae* in London, 485.
- Kentucky: Classification of Vines liable to Damage by Frost, 384.
- Kernel Smut: Of Sorghum (*Sphacelotheca Sorghi*), 760.
- Kernel Spot: Of Pecan (*Carya olivaeformis*) caused by *Coniothyrium caryogenum*, 927.
- Kerria japonica*: *Helicobasidium Tanakae* in Japan, 705.
- "Khakibos" (Mexican Marigold), *Tagetes minuta*, in Rhodesia, 932.
- "Khaki Weed" (*Alternanthera echinata*), 932.
- "Kharif", Crops, in Sindh (India), 484.
- "Kherol", (*Euphorbia hypericifolia*), 484.
- Kiri Tree, in Japan, 705.
- "Kloverspetsviveln" (*Apion apri-cans*), 241.
- "K'neili tzu" Chinese Chestnut Resistant to "Bark Disease", introduced into U. S. A., 138.
- "Koltrosten" (*Turdus merula*), 241.

- "Koori" (*Solanum Dallachii*, [*S. largiflorum*], 364).
- "Kornbladflue" (*Hydrellia griseola*), 476.
- "Kornbladlusen" (*Macrosiphum graminum*), 476.
- "Koinflugan" (*Siphonophora* [*Chlorops*] *pumilionis*), 241.
- "Kråken" (*Corvus cornix*), 241.
- "Kuwa no Rinmonbyô" (Circle Blotch of Mulberry), (*Phyllosticta* [*Phoma*] *kuwacola*), 705.
- Kuwania gorodetskii*: On Birch in England, 485.
- LACE BARK, (*Hohenia populnea*): *Puccinia Hoheniae*, 228.
- Lachnosterna grandis*: On *Oxyccus macrocarpus*, in U. S. A., 495.
- Laemophiloeus* sp.: Pest in Food Stores in Java, 1438.
- Laestadia cambucæ*: On *Martheria edulis*, in Brazil, 586.
- "Lagarta" (Larvæ of Gipsy Moth, *Porthetria dispar*) in Spain, 1432.
- Lagerstroemia indica*: Damage done by Tarring Streets of Milan (Italy), 584.
- Lamium* sp.: Damage done by Tarring Streets of Milan (Italy), 584.
- Laphygma frugiperda*: On Cranberry in U. S. A., 495.
- Larix occidentalis*: Attacked by *Eccoptogaster unispinosus* in Oregon, 114.
- Larch Canker, (*Dasyscypha Willkommi*) 771.
- Large White Cabbage Moth (*Pieris brassicæ*) in France, 370, 603.
- Larkspur, Tall, Eradication on Cattle Ranges in U. S. National Forests, 55.
- Larus canis* in Sweden, 241.
- Laser, Bacillus of, 1316.
- Lasioderma serricornis*: Pest in Stored Food Stuff in Java, 1438. On Tobacco in Dutch East Indies, 1436.
- Lasiopoda carpophila* and *L. kreff-*  
*riana*: On *Olea europæa* in Italy, 945.
- Lasius*: Gen. Formicidæ, in Hérault, 366.
- Laspeyresia caryana*: On Pecan in U. S. A., 496.
- Laternæa colummata*: On Sugar Cane in Tropical, Sub-Tropical America, especially W. Indies, 1057.
- Lathyrus sativus* (Chickling Vetch): *Acanthoscelides obiectus*, in Italy, 606.
- Laurel: *Autographa californica*, Alfalfa Looper, in Brit Columbia, 1062. Damage done by Tarring Streets of Milan (Italy), 584. *Trioxa alacris*, Injurious Hemipteron in New Jersey, 1064.
- Lawsonia alba*: *Lecanium* (*Saissetia*) *nigrum* in Coimbatore, 242.
- Leaf-Bugs (Mirids): *Heterocordylus malinus*, *Lygidea mendax*, *Neurocolpus nubilis*, *Paracalocoris colon*, on Apple in Ontario, 247.
- Lecanium*: *L. adersi* with *Aspidiotus destructor*; On Mango in Zanzibar, 242. *L. (Akerms)* sp. on *Hura crepitans* associated with *Ceroplastes curripediformis* in Brit. Guiana, 242. *L. bituberculatum* and *L. corni*, 244. *L. (Saissetia) cuneiformis*; On *Acokanthera* sp. Brit. E. Africa, 242. *L. elongatum* in S. Africa, 244. *L. hemisphaerium* in Brit. E. Africa, 242; On *Adiantum*, *Aristolochia* and Coffee in Uganda, 242. *L. hesperidum* in S. Africa, 244; On Orange in France, 821. *L. (Coccus) hesperidum*; On Banana, and Citron in Brit. E. Africa 242. *L. nigrum*; On *Ficus* sp.: in São Thomé, 609. *L. (Saissetia) nigrum*; On Coffee in Uganda, on Cotton in Coimbatore, on *Lawsonia alba* in Coimbatore, on Ornamental shrub in Brit. E. Africa, 242. *L. oleæ* with *Capnodium meridionale*; On Olive in S. France, 821. *L. (Eulecanium) somereni*;

- On *Erythrina excelsa* in Uganda, 242. *L. (Eucalymnatus) tessallatum*; In Malacca Apple, associated with *L. wardi*, in Brit. Guiana, 242. *L. viride*; On Coffee in São Thomé, 609. *L. (Coccus) viride*; On Liberian Coffee in Brit. Guiana and S. Africa, 242.
- Leguminosae: *Grapholitha nigricana*, *Physopus robusta* and *Sitona lineata*, in Sweden, 241.
- Lemmus lemmus*: In Sweden, 241.
- Leperisimus aculeatus* (= *Hylesinus aculeatus*), in Oregon, 114.
- Lepidiotia albohirta* and *L. frenchi*: On Sugar Cane in Queensland, 246.
- Lepidium apetalum* (Pepper Grass): Amongst Cereals, in Montana, 639. Secondary Host of *Myzus cerasi* in Ontario, 368.
- Lepidosaphes*: *L. beckii*: Attacked by *Aspidiotiphagus citrinus*, 118; On *Citrus* spp. in Uganda, 243. *L. citricola* (= *L. beckii*), 243. *L. desmidioides*; On *Nephrodium* sp. in England, 485. *L. gloveri*: In S. Africa, 244; On *Citrus* in Uganda, 243, On *Codiaeum* in Uganda, 242, 243, On Oranges imported into Grt Britain, 485. *L. pinniformis*; On Citrus, Croton and *Murraya*, in S. Africa, 244. *L. ulmi*: On Cranberry, in U. S. A., 495, On Apple, Pear and Plum in Ontario, (Oyster Shell Scale), 247.
- Leptinotarsa decemlineata*, (Potato Beetle), 774.
- Leptocoris varicornis*: On Rice in Assam, 604.
- Leptosphaeria Sacchari*: On Sugar Cane in Tropical and Sub-Tropical America, especially W. Indies, 1057.
- Lepus europaeus* and *L. timidus*: On Fruit Trees in Sweden, 241.
- Lesser Apple Worm (*Enarmonia prunivora*), 247.
- Lettuce: *Agriolimax agrestis*, in N. York State, 943. *Autographa californica* in Brit. Columbia, 1062. *Euxoa excellens* in Brit. Columbia, 494. *Scapteriscus vicinus*, in Porto Rico, 1063. *Sclerotinia Libertiana*, in Florida, 583.
- Lettuce Drop (*Sclerotinia Libertiana*), in Florida, 583.
- Leucaena glauca*: Use in Control of *Imperata arundinacea*, in the Philippines, 1123.
- Leucaspis signoreti*: *Aspidiotiphagus citrinus*, 118.
- Leucotermes flavipes*: (White Ant) Pecan in U. S. A., 496.
- Liberia: *Cylas femoralis*: On Sweet Potato, 936.
- Libocedrus decurrens*; Host of *Phloeosinus punctatus* in Oregon, 114.
- Lignum vitae: *Aleurothrixus (Aleurothrixus) floccosus* and *A. (A.) howardi*, in Jamaica, 933.
- "Ligusterbladlusen" (*Siphocoryne ligustri*), 241.
- "Lila" (*Melia sempervirens*), 722.
- Lilium longiflorum*: *Botrytis Liliorum* in Japan, 705.
- "Lilla krusbärsstekeln" (*Pristiphora appendiculata*), 241.
- Limax agrestis*: On Potatoes in Norway 476.
- "Limberger" Red Grape resistant Mildew, 105.
- "Lindmätaren" (*Hibernia defoliaria*), 718.
- Liparis monacha*: On Forest Trees in Sweden, 718.
- "Lionzi" in Belgian Congo, 940.
- Lithraea caustica*: *Aleuroparadoxus punctatus*, in Chile, 933.
- Little Hickory Aphid (*Monellia caryella*), 496.
- "Little Marvel" Var. Pea subject to *Pseudomonas seminum* in England, 495.
- Livingstonea* spp; *Scapteriscus vicinus*, in Porto Rico, 1063.

- Lixus iridis*: On Celery in Hérault, 366.
- Locusts: *Canis zerda* (Fennec Fox as Destroyer, 1266. Breeding Place *Imperata exaltata* (Cocon Grass) in the Philippines, 53. Control in Capitanata in 1917, with Use of Cresosol and Sodium Arsenite Sprayings, Poisoned Bran, and Cloths; Vars: found, (*Calliptamus* [*Docistaurus*] *maroccanus*, *Oedipoda* and *Stenobothrus*) and Details of Distribution, 1311. Control, in Italy, 1291. Grasshoppers on Sorghum, in Kansas, U. S. A., 760.
- Lodging: Resistant Vars of Oats and Barley in Norway, 855. Selection of Cereals in Sweden, 143. Selected Wheat in India, 854.
- Lolium*: Damage done by Tarring Streets of Milan, (Italy), 584.
- Lonchaea aristella*: On Fig and Wild Fig in Italy, 716. On Wild Fig in Italy, 249.
- Long Island: Insects injurious to Cranberry (*Oxycoccus macrocarpus*), 495.
- Lophodermium juniperinum*: In New Jersey, 1307.
- Lophyrus pini* and *L. sertifer*: On Forest Trees in Sweden, 718.
- Loranthus*: *Aleurolobus flavus*, *Dialeurodes* (*Rabdostigma*) *radiilinealis*, and *D. (Rachispora)* *rutherfordi* in Ceylon, 933. *Meliola catubigensis* in the Philippines, 587.
- Louisiana: *Aleyrodidae*, 933. *Cylas formicarius* var. *elegantulus* on Sweet Potato, 936.
- "Lövvvedborren" (*Anisandrus* [*Xyleborus*, *Scolytus*, *Tomicus*] *dispar*), 241.
- "Lövvivlar" (*Phyllobius* sp., 241.
- Loxia curvirostra*, In Sweden, 241.
- Lucerne: Alfalfa Looper (*Autographa californica*) in Canada, 1062.
- Aplids, *Cuscuta* and Leaf Rust (*Uromyces striatus*), Attacks in the Oasis of Tripoli, 163.
- "Lulur" (*Digeria arvensis*), 484.
- Lupin: *Autographa californica*; in Brit. Columbia, 1062 *Lupinus albus* attacked by *Acanthoscelides oblectus*, 606.
- Lycidocoris*: *L. mimeticus* var. A. in Uganda; var. B., On Coffee, in Belgian Congo; *L. modestus*; On *Cinchona*, and *L. thoracicus*; On Indigenous Rubiaceous Plant in Belgian Congo, 940.
- Lyda hieroglyphica*: On Forest Trees in Sweden, 718.
- Lygidea mendax*: On Apple in Ontario, 247.
- Lygus pratensis*: On Cabbage and Turnip, in Sweden, 241.
- Lyonieta clerkella*: On Fruit Trees in Sweden, 241.
- Lysol: Experiments in Disinfection of Dwarf Beans infected with *Acanthoscelides oblectus* and *Spermophagus subfasciatus*, 605.
- Lytophilus melanocephalus*: Parasitic on Undertermined Lepidopterous larva, (*Colias lesbia*?) injurious to Lucerne in S. Brazil, 714.
- MACROSIPHUM: *M. dahliifolii*; On Dahlia in Uganda, 487. *M. granarium*; On Cereals in Norway, 476. *M. illinoisensis*; Life History, 367. *M. sonchi*; On *Centaurea* and *Cichorium* in S. E. Russia, 1180.
- Macrosporium somniferi*, On *Papaver somniferum* in Podolia, 349.
- Madagascar: *Aleyrodidae*, 933.
- Madeira: *Aspidiotiphagus lounsburyi* Nat. Enemy of *Fiorina fioriniæ* on an Undertermined Plant, 118.
- Madras: Coccidae, 242. Damage done by Tarring Streets of Milan (Italy), 584.
- Magnesium Carbonate: Injurious Action on Plants, 969.
- Magnolia grandiflora*: Damage done

- by Tarring Streets of Milan (Italy), 584.
- "Magyar Traube", Red Grape offering Relative Resistance to Mildew, 105.
- Maize: *Acanthoscelides obtectus*, 606. *Autographa californica* in U. S. A., 1062. Maize Caterpillar in Queensland, 28. *Polycystus clypeatus* One female reared from a Leafminer in St. Vincent, W. Indies, 934. *Sclerospora macrospora* In Eritrea, 477; In Italy, 1053. Selection of Vars. resistant to "Smut", (*Ustilago Zeae*, Beck), in U. S. A., 1099. Sweet Maize: Vars: resistant to Earworm (*Chloridea obsoleta*), in U. S. A., 279.
- Maize Caterpillar, 28.
- Malacca: Fungi in Singapore, 1173.
- Malacosoma: *M. americana*, and *M. disstria*; On Apple, Pear, Plum, Peach in Ontario, 247. *M. neustria*; On Fruit Trees in Sweden, 241.
- Malay States, Federated: Danger of burying Felled Coconut Trees between rows of Rubber Trees, owing to infection by *Fomes lucidus*, *Hymenochaete noxia* and *hypolateritia*, 1056. Fungi, 1295.
- Malus sylvestris*: Effects of Soil Water Supply on Apple Spot Diseases U. S. A. 1048.
- Malva sylvestris*: *Puccinia Malvacearum* in the Andes, S. America, 926.

- Mammals: Injurious Specimens in Sweden, 241.
- Mandarines see Citron Fruits.
- "Mandhani" (*Eleusine aegyptiaca*), 484.
- Mangifera indica*: *Aleurocanthus woglumi*, in Cuba, 1186. *Meliola Mangiferae* in Singapore, 1173.
- Mango: Attacked by *Aleurocanthus mangiferae* in India, 933. *Aspidiotus cydoniae* in Brit. E. Africa, 242. *A. destructor*, On Gold Coast and in Zanzibar, 242. In Uganda, 242, 243. *A. (Chrysomphalus) ficus*, in Coimbatore, 242. *A. (Pseudonidia) trilobitiformis*, in Uganda, 242. *Ceroplastes rubens*, in S. India, 242. *Chrysomphalus dictyospermi*, in Uganda, 243. *Dialeurodes (Rusotigma) radiirugosa*, in Dutch. E. Indies, 933. *Icerya seychellarum*, in Uganda, 242, 243. *Lecanium adersi*, in Zanzibar, (in association with *A. destructor*), 242. *Pseudonidia trilobitiformis* in Uganda, 243. *Pulvinaria psidii* in Coimbatore, 242.
- Manihot: *M. Aypi*: *Helminthosporium Manihotis* in Brazil, 586. *M. Glaziovii*: *Aspidiotus destructor* in Uganda, 242. *M. utilissima*: *Aleurothrixus (Aleurothrixus) aëpim*, in Brazil, 933. *Pseudococcus virgatus*: On Cassava in Zanzibar, 242.
- Manitoba (Canada): *Autographa californica*, 1062.
- Marasmius Sacchari* and *M. stenophyllus*: On Sugar Cane in Tropical, Sub-Tropical America especially the W. Indies, 1057.
- "Marciume radicale" (Root Rot), of Citrus in Oasis of Tripoli, 1292.
- "Märgborrarna" (*Myelophilus minor*, *M. piniperda*), 718.
- Markhamia platycalyx* (= *Dolichandrone platycalyx*): *Stictococcus multispinosus* in Uganda, 242.
- Martiereae edulis*: *Laestadia cambucæ* and *Puccinia cambucæ* in Brazil, 586.
- Marssonina bracteosa*: On Leaves of *Ribes bracteosum* attacked by *Gloeosporium Bartholomæi*, in Washington State, 103.
- "Martsgallvecklaren" (*Tortrix resinella*), 718.
- Maryland: *Macrosiphum illinoensis*, 367.

- Masicera* sp; On *Gelechia ocellatella*, in Italy, 1315.
- Massachusetts: 'Asparagus Selection, Vars. resistant to Rust (*Puccinia Asparagi*, 285. Insects Injurious to Cranberry, (*Oxycoccus macrocarpus*), 495.
- Massaria japonica* and *M. moricola*: On *Morus alba* in Japan, 102.
- Mastigosporium album* var. *muticum*: On *Dactylis glomerata* in England, 1424.
- Matayba apetala*: *Aspidiotus* (*Pseudonidia*) *tesseratus* in Jamaica, 242.
- Maurice Baco 22A (Folle Blanche × Noah) Vine Hybrid resistant to *Botrytis cinerea* in France, 519.
- Mauritius: Pests observed on Tobacco ("Tabac bleu") from Réunion; *Achatina ponderosa*, *Heliothis armigera*, *Heterodera*, *Pythium de Baryanum*, Cultivation Experiments, 942. *Pseudonidia trilobitiformis*; On *Nephelium Lit-chi* (Probably ex-Mauritius), 244.
- Mealy-Bug (*Pseudococcus adonidum*), on Cranberry, U. S. A., 495.
- Measures, Legislative and administrative: International Yearbook of Agricultural Legislation, 7th Year (1916). Italy: Control of Locusts, 1918, 1291. Trinidad and Tobago: Order of Govt. Placing the Coconut Butterfly (*Brassolis sophorae*) among Plant Pests, 171.
- Meckelia flava*: *Dialeurodes* (*Gigaleurodes*) *struthanti*, in Brazil, 933.
- Medlar: *Olethreutes variegana*, In Italy, 611. Japanese Medlar: Winter Treatment with Lime Sulphur pray against *Fusicladium pirinum* var. *Eriobotryae* in Italy, 599.
- Megaclinium falcatum*: *Aspidiotus articulatus* in São Thomé, 609.
- Megastigmus ballestrerii* (= *Trogocarpus ballestrerii*); On Pistachio and Turpentine Tree, in Sicily, 831.
- Megastoma*: On Field Mice in Italy, 1318.
- Melampsora Ricini*: On *Ricinus communis* β *africanus* in Eritrea, 477.
- Melanconium saccharinum*, and *M. Sacchari* (= *Darlucella melaspora*): On Sugar Cane in Tropical and Sub-Tropical America Especially the W. Indies, 1057.
- Melanoplus bivittatus*: On *Oxycoccus macrocarpus*, in U. S. A., 495.
- "Melascone nera" Red Grape Var; offering Relative Resistance to Mildew, 105.
- Melasmia Menziesiae*: On *Menziesia ferruginea*, in State of Washington, 103.
- Melasoma aenea*: On Forest Trees in Sweden, 718.
- Melia*: *M. Azedarach*: *Septobasidium Acaciae* in Japan, 705. *M. sempervirens*: *Phymata noualhieri* in Mexico, 722.
- Meliola*: In Singapore; *M. aethiops*; On *Cassia Fistula*, *M. Mangiferae*; on *Mangifera indica*, and *M. mangostana*; On *Garcinia Mangostana*, 1173.
- Melilotus*: *M. alba*; Medium for *Pycnidia* of *Fusicoccum putrefaciens*, 237. *M. officinalis*: Host of *Aphis laburni* in S. E. Russia, 1180. *Melilotus* sp.: *Autographa californica* in U. S. A., 1062.
- Meliola catubigensis*: On *Loranthus* in the Philippines, 587.
- Melolontha* sp.: On Cereals in Sweden, 241.
- Melothria indica*: *Uredo cantonensis*, in S. China, 350.
- Membracis subulata* (= *Stictolobus subulatus*), 1067.
- Menziesia ferruginea*: *Melasmia Menziesiae* in State of Washington, 103.
- Merulius Pinastri*, in Great Britain, 1424.
- "Meslier Saint-François" or "Meslier du Gâtinais", "Meslier hâtif",

- and "Meslier rose", White Grape Vars; offering Relative Resistance to Mildew, 105.
- Metataphus torquatus*, 1059.
- Metarrhizium Anisopliae*: On *Tomaspis saccharina*, in Grenada, 939.
- Meleorus versicolor*: On *Euprocitis chrysorrhoea*, imported into U. S. A. from Europe, 1433.
- Mexican Marigold (Mexican Poppy) (*Tagetes minuta*); Weed in Rhodesia, 932.
- Mexico: *Acanthoscelides obtectus*, 606. *Aecidium Gossypii*, 479. *Aleyrodidae*, 933. *Andricus dugesi*, 124. *Amphibolips nigra*: On *Quercus* sp., 124. *Phymata noualhieri*, Hemipterous Enemy of *Musca domestica*, On *Melia sempervirens*, 722. *Ptychodes trilineatus*, On Fig, 248.
- Michigan: *Tylenchus penetrans* on Potato, 491.
- Miconia* sp.: *Septoria Miconiae* in Brazil, 586.
- Microcotermeus parvus*, subsp. *theobromae*, On Cacao in São Thomé, 609.
- Microdus*: *M. diatraeae*; On *Diatraea saccharalis* in Brit. Guiana, 935. *M. mediator*: Nat. Enemy of *Coleophora fuscedinella*, in Sweden, 615.
- Microplitis alaskensis* and *Microplitis* sp.: On *Autographa californica*, in Brit. Columbia, 1062.
- Mildew: Of Cereals (*Sclerospora macrospora*): On Maize, in Piedmont, 1053. Of Hemp: (*Peronosplasma camabina*): in Italy, 107. Of Melon (*Plasmopara cubensis*); 107. Of Onions: (*Peronospora Schleideni*), in Indiana, 422. Of Potato (*Phytophthora infestans*); "New Era" Var; immune to Attack, 138. Of Vine (*Plasmopara viticola*). Comparison between Effects of Copper Mixtures and Acid Mixtures, 590; Copper Sulphate, Simple Solutions Control Method, 822; Defence against Vine Mildew; Organisation by the Phytopathological Observatory of Turin (Italy), 925; Direct Bearers and their Resistant Qualities, Hérault, 1250; Downy Mildew in Australia, 359; Downy and Powdery Mildews in E. America, 425; Effect of Pruning on Resisting Power of Grafted Vines, France, 1251; French Vines offering Relative Resistance to Mildew, 105. Hybrid Bearers and Resistant Qualities, 303, 519, 770; Polysulphide Action, (Liver of Sulphur), 931;
- Mildew, Hop, (*Sphaerotheca Humuli*): Resistant Forms of Hop in England, 232. Wild Hop of Japan (*Humulus Lupulus* var. *cordifolius*) Attacked in England, 232.
- "Mindre äpplevecklaren" (*Enarmma prunivora*?) "M. knoppvecklaren" (*Imetocera ocellana*), "M. korsnabben" (*Loxia curvirostris*), "M. margborren" (*Myelophilus minor*), 241.
- Mineola vaccini*: On *Oxycoccus macrocarpus*, in U. S. A., 495.
- "Minnesota. No. 1017". Var. Strawberry showing Slight Resistance to Cryptogamic Diseases, 298.
- Miotropis sulcicrista*: Nat. Enemy of *Coleophora fuscedinella*, in Sweden, 615.
- Mirids, (Leaf Bugs): *Heterocordylus malinus*, *Lygidea mendax*, *Neurocolpus nubilus*, *Paracalocoris colon*, 247.
- Mississippi: *Aleyrodidae*, 933. *Macrosiphum illinoensis*, 367.
- Missouri: *Macrosiphum illinoensis*, 367.
- Mites: Fam. *Gamasidae*; On Field Mice in Italy, 1318. Mite Disease of Potato, in Hawaii, 1314.
- Mixtures, Spraying. Comparison between Effects of Copper and Acid

- Mixtures on Mildew of Vine, 590.  
 Lime Sulphur: (Spraying against *Fusicladium pirinum* var. *Eriobotryae*, Injurious to Japanese Medlar, Formula of the Stazione di Agrumicoltura of Acireale, in Italy, 599, 826.  
 Strong L. S. Spraying against *Chrysomphalus dictyospermi* injurious to Citrus, 613.  
 "Mjölktistelbladlusen" (*Rhopalosiphum lactucae*), 241.  
*Monellia caryella*: On Pecan in U. S. A., 496.  
 "Mongoose" (*Herpestes*) in Grenada, 939.  
*Monilia* sp.: Cause of Specific Gummosis of Apricot Tree in Italy, 598.  
*Monodontomerus aereus*: Nat. Enemy of *Euprocis chrysorrhoea* in U. S. A., 1433.  
*Monodora Myristica*: *Icerya seychellarum* in Uganda, 242.  
*Mononychus punctum-album*: On *Iris florentina*, *I. foetidissima*, *I. germanica*, *I. Pseudacorus*, in Hérault, 602.  
*Monophlebus vaddoni*: On Unknown Plant in Uganda, 243.  
 Monsoon Sorghum Crop: Liable to Smut in Pres. Bombay, 1054.  
 Montana (U. S. A.): Harmful Weeds amongst Cereals, 639. *Autographa californica*, 1062.  
*Morganella maskelli*: On Citrus etc. in S. Africa, 244.  
 Morocco: *Pyrus mamorensis*, Resistant to Drought, in Forests of Mamora, 1086.  
 "Morotbladloppan" (*Trioza viridula*), 241.  
 "Morotfluga" (*Psila rosae*), 241.  
*Morus*: In India: *Aleuroplatus* (*Aleuroplatus*) *pectiniferus* and *Dialeurodes* (*Dialeuropa*) *decempuncta*, 933. In Japan: *Massaria japonica* and *M. moricola*, 102; *Nothopatella moricola*; *Phyllosticta*: (*Phoma*) *kuwacola*: and *Ustilina Mori*, 705. In Uganda: *Eulecanium somereni*, 213. *Morus* sp.: In Jamaica: *Pulvinaria cupanae*, 242. In Japan: *Helicobasidium Tanakae*, 705. In Uganda; *Stelococcus diversiseta*, 213.  
 "Mosaic Disease": Of Sweet Potato, 864.  
 "Mosca nera del fico" (*Lonchaea aristella*), 716.  
 "Mosca prieta" (*Aleurocanthus woglumi*), 1186.  
*Mosquilla vastatrix*: Hemipteron on Cacao in State of Bahia (Brazil), 493.  
 "Mottled Leaf": Of Citrus Plants, 173.  
 "Motling Disease": Of Sugar Cane, 1057.  
 Motling: On Citron Plants; In California, 173, Composition of Citron Leaves at Various Stages of Disease, 743.  
 "Mullvaden" (*Talpa europaea*), 241.  
 "Mullvadssyrsan" (*Gryllotalpa gryllotalpa*), 241.

*Mus agrarius*: *Bacillus "Iaser"* *Mus sylvaticus*: *Bacterium muris*, 1316, 1318. *Mus agrestis*. In Sweden 241. *Mus arvalis*: *Bacterium microli* in the Carso, 1318.  
 "Mwanga", 242.  
*Mycosphaerella*: *M. citrullina* (Stem Blight); On Watermelon, in U. S. A, 238. *M. Horii*; On Citrus spp. in Japan, 102.  
*Mycovellosiella*, 586.  
*Myelophilus minor* and *M. piniperda*: On Forest Trees in Sweden, 241.  
*Myrmaridae*, 1059.  
*Myrica* sp. (?): *Aleuroplatus* (*Aleuroplatus*) *miricae* in Georgia, 933.  
*Myrmecophila acervorum*: Living on

- Formicidae (Gen. *Camponotus*, *Formica*, *Lasius*, *Myrmica*, *Tetramorium*, *Solenopsis*) in Hérault, 366.
- Myrobalan: "Verde-secco" of Fruit Trees in Apulia, (Italy), 597.
- Mysore: Spike Disease of Sandalwood (*Santalum album*), 5. Southern Mysore: Coccidae; *Hemilecanium imbricans* on *Cedrela Toona*, 242.
- Mytilaspis* (*Lepidosaphes*) *citricola*: On Lime Tree, at Accra (Gold Coast), 242.
- Myxomycetes: In Ceylon, 704; In Prov. of Verona, (Italy), 1172.
- Myzoxylus laniger* (= *Schizoneura lanigera*), In Italy, 630.
- Myzus*: *M. cerasi*; On Cherry in Ontario, 247; On *Lepidium apetalum* (Secondary Host). Colonies also established on *Brassica arvensis*, *Capsella Bursa-pastoris*, *Erysimum cheiranthoides*, in Ontario, 368; On Wild Cherry in S. E. Russia, 1180. *M. pterisoides*: On Ferns at Kampala, (Uganda), 487.
- NATAL: Coccids introduced in 1917, 244.
- "Natalino" (Fig): *Lonchaea aristella* in Italy, 716.
- "Ne Plus Ultra" Var. of Peas Subject to *Pseudomonas seminum*, in England, 595.
- Necrobia rufipes*; Pest in Stored Food Stuffs in Java, 1438.
- Nectandra* sp.; *Aleuroplatus* (*Aleuroplatus*) *vinsonioides*, in Cuba, 933. *N. coriacea*: *Aspidiotus cydoniae* and *A. (Pseudaonidia) tesseraeus* in Jamaica, 242.
- Nectria*: *N. fusco-purpurea*; On Plums (var. Pond's Seedling) in England, 1424. *N. Laurentiana*; On Sugar Cane in Tropical and Sub-Tropical America Especially the W. Indies, 1057. *Nectria* (?) sp.; Nat. Enemy of *Aspidiotus* (*Chrysomphalus*) *aurantii*, in Brit. E. Africa and S. Rhodesia, 242.
- Negundo aceroides*: Damage done by Tarring Streets of Milan (Italy), 584.
- Neomaskellia*: *N. bergii* on Unknown Host in Java and 933 on Wild Grass in Manila, Philippines, *N. comata*, 933.
- Neomphaloidella ceroplastae*: On *Ceroplastes galeatus*, in Uganda, 243.
- Neotermes gestri*: On Cacao in São Thomé, 609.
- Nephelium Lit-chi*: *Pseudaonidia trilobitiformis* in S. Africa, 244.
- Nephrodium* sp.: Damage done by Tarring Streets of Milan (Italy), 584. *Lepidosaphes desmidioides* in England, 485.
- Nephrolepis*: Host of *Hemichionaspis aspidistrae* attacked by *Aspidiotiphagus lounsburyi*, in Italy, 118.
- Nerium*: *Aspidiotus cydoniae* on Gold Coast, 242. *A. (Pseudaonidia) trilobitiformis*, in Uganda, 242.
- Nettle Tree: Disease Observed in Italy, 1283.
- Neumann, Bacillus of, 1316.
- Neurocolpus nubilus*: On Apple, in Ontario, 247.
- Nevada (U. S. A.): *Autographa californica*, 1062.
- Nevis: *Euscepes batatae*; On Sweet Potato, 936.
- "New Era" Var. Potato immune to Potato Blight (*Phytophthora infestans*) imported into U. S. A. from N. Zealand, 138.
- New Hampshire: Disease of Hemlock Tree (*Fomitiporia tsugina*), 110.
- New Jersey: *Aleyrodidae*, 933. *Corythucha spinosa*; On *Prunus serotina*, 717. Injurious Insects on Cranberry, *Oxycoccus macrocarpus*, 495. *Keithia Chamaecyparissi*; On *Chamaecyparis thyoides*, 1307. *Macrosiphum illinoisensis*, 367. *Trioxa alacris*; On Laurel, 1064.

- New York, State of: *Agriolimax agrestis*, On Vegetables, 943. *Autographa californica* (?), 1062. *Fomitiporia tsugina*, On *Tsuga canadensis*, 110. *Macrosiphum illinoensis*, 367. *Tylenchus penetrans*, On Roots of *Viola* spp, 491. *Vinifera* Grapes and Mildew, 425.
- New Mexico: Rest and Smuts collected in 1916, 585.
- New South Wales: *Kennedya rubicunda* Leguminous Plant injurious to Forest Trees, 239.
- New Zealand: Resistant Vars, of Wheat to Rust, to *Tilletia levis* and *T. Tritici*, and "Ruakura Rust Resistant". Oat, 519. *Aleyrodidae*, 933. Fungi: *Puccinia Hoheriae*; On Leaves and Stem of *Hoheria populnea* (Lacebark), 228.
- Nezara viridula* of Pecan and Cow Pea causing *Coniothyrium caryogenum*, in Georgia, 927.
- Nicaragua: *Acanthoscelides oblectus*, 606. *Phychodes trilineatus* on Fig, 248.
- Nicotiana: *N. Tabacum*: *Cercospora solanicola* in Brazil, 1058. *N. tomentosa*: *Puccinia Nicotianae* in Andes S. America, 926. *Nicotiana* sp.: *Cercospora Raciborski* in Eritrea, 477.
- Nigella*: *Aphis* sp. in S. E. Russia, 1180.
- Nigeria: *Bagnisiopsis Dioscoreae* Parasite of *Dioscorea praehensilis*, 1304. Coccids, 242. *Physothrips funtuniae*; On *Funtumia elastica*, 937. *Nigrospora Panici*: On Wheat in Java, 1426.
- "Nonne" (*Lymantria monacha*), 476.
- Norfolk Island: *Euscepes batatae* on Sweet Potato, 936.
- Norway: Insects and Animals injurious to Cultivated Plants 1916, 476. Oat Vars: Resistant to Lodging, 855.
- Nothoplatella moricola*: On *Morus alba* in Japan, 705.
- Novius cardinalis*: Nat. Enemy of *Icerya purchasi*, in S. Africa, 244.
- "Nsambyia": *Pulvinaria psidii*, in Brit. E. Africa, 242.
- "Nunnan" (*Liparis monachus*), 718.
- Nut Weevils (*Balaninus nucum*), 611.

- Nysius ericae* (= *N. angustatus*) False Chinch Bug: On Sugar Beets and Cruciferous Garden Crops, in U. S. A., 1185.
- OAK: *Coleophora fuscedinella*; in Sweden, 615. *Diaporthe taleola* in Switzerland, 362. *Dryobius croaticus* in S. E. Russia, 1180. *Grotiusomyia flavicornis* reared from a Pyralid Leaf Miner in Washington, D. C. 934. *Phyllactinia suffulta*, in Spain, 601. *Porthetria dispar* in Spain, 1432. See also *Quercus*.
- Oak Cossid (*Cossula magnifica*), 496.
- Oak Pruner (*Elaphidion villosum*), 496.
- Oats: *Agriotes lineatus* in Sweden, 241. *Cicadula sexnotata*. Injuries in Sweden, 1313. *Hydrellia griseola* in Norway, 476. Locust Attacks in Capitanata, 1917, 1311.
- Norwegian Vars. Resistant to "Lodging", 855. *Oscinella frut* in Norway, 476. *Tipula oleracea* in Norway, 476. Varieties resistant to *Ustilago Avenae* in U. S. A., 519. *Ustilago levis* in New Mexico, 1916, 585.
- Ochra pulchella*: *Ceroplastes ficus* in S. Africa, 242.
- Ocymum sanctum*: *Ceroplastodes cajan* in Coimbatore, 242.
- Odontia: On *Paspalum*: *O. saccharicola* in Porto Rico, 1176. On sugar Cane; *O. Sacchari* and *O. saccharicola* in Porto Rico, 1176; and in Tropical, Sub-Tropical America, Especially the W. Indies, 1057.
- Oedipoda*: In Capitanata (Italy), 1311.
- Oiceticus*: *Heptasnicra brasiliensis* and

- Tetrastichus isis*: Possible Parasites in S. Brazil, 714.
- Oidium of Vine, (*Uncinula necator*): "Gros Pinot Blanc Hâtif". Very resistant var., 105. Hybrid Bearers in France and their Resistant Qualities, 303, 519, 770. Lime Sulphur Spray und Bordeaux Mixture compared with Polysulphide, 931. Resistant Vars: and Vars: liable to Attack, 519. On *Vitis hercynica* in U. S. A., 232.
- Oidium* spp.: In Ceylon, 704; *Oidium farinosum*, 630.
- Oklahoma: *Macrosiphum illinoensis*, 367.
- Olea*: *O. chrysophylla*; *Cecidomyiidae* in Eritrea, 945. *O. europaea*: *Cecidomyiidae* in Italy, 945.
- Oleander: *Pseudoaonidia trilobitiformis* in Uganda, 243.
- Olethreutes variegana*: On Fruit Trees in Italy; Morphological and Biological Description, 611.
- Olive: *Aleurolobus olivinus*, in Italy, 933. *Capnodium meridionale*, in France, 821. *Cecidomyiidae*, living on *Olea chrysophylla* in Eritrea and on *O. europaea* in Italy, 945. *Lecanium oleae*, in France, 821. Locusts in Capitanata, (Italy) in 1917, 1311. *Opius concolor*, Parasite of the Olive Fly "*Dacus oleae*", Acclimatisation Experiments in Italy, 1181. "Verdessecco" of Fruit Trees in Apulia, (Italy), 497.
- Olive Fly, (*Dacus oleae*): In Italy, parasitised by *Opius concolor*, 1181.
- Omphalchrysocharis petiolatus*, Reared from an Oscinid: On a Daisy, at Washington, D. C., 934.
- Oncideres cingulatus*: On Pecan in U. S. A., 496.
- Onion: *Agriotes lineatus* in Sweden, 241. *Autographa californica*, in Brit. Columbia, 1062. *Euxoa excelsa* (Cutworm), in Brit. Columbia, 494. Insect Pests and Diseases in Indiana, 422.
- Onion Mildew (*Peronospora Schleideni*), 422.
- Onophilus carideri*: Nat. Enemy of *Pulvinaria flavescentis*, *P. minima* and *P. platensis* in the Argentine, 1308.
- Ontario (Canada): *Lepidium cerasi* Secondary Host of *Myzus cerasi* (Colonies also established on *Capsella Bursa-pastoris*, *Brassica arvensis* and *Erysimum cheiranthoides*), 368. Pests on Fruit Trees, 247. Principal Diseases of Vegetables, 709.
- Oospora Scabies* (Potato Scab); Use of Mercuric Chloride as Control, 491.
- Opuntia monacantha*: *Coccus confusus capensis* and *C. indicus* in S. Africa, 244.
- Orange see Citron Fruits.
- Orange Free State: Coccids introduced in 1917, 244.
- Orange White Fly (*Dialeurodes* [*Dialeurodes*] *citri*, 476.
- "Orangegule hvetemy" (*Cecidomyia aurantiaca*), 476.
- Orchid: Species living on *Caesalpinia coriaria*, in the Dominican Republic, 1363.
- Orcus calibaeus*: On *Chrysomphalus dictyospermi*, 118.
- Oregon: *Autographa californica*, 1062, Scolytid Beetles, 114.
- Organic Compounds, Toxicity to Insects, 774.
- Orihezia insignis*: On Coffee in São Thomé, 609. In S. Africa, (Sporadic in Natal Midlands), 244.
- Orthotomicus ornatus*: On *Pinus ponderosa* in Oregon, 114.
- Oscinella frit*: On Barley and Oats in Norway, 476. *O. (Oscinis) frit*: On Cereals in Sweden, 241.
- Oscinosoma discretum*: On Fruit of Wild Figs, in Italy, 249.

*Osmaronia cerasiformis*: Attacked by *Septogloeum Nuttallii*, in Vancouver Island, 103.

*Ostodes zeylanica*: *Aleuroplatus* (*Aleuroplatus*) *incisus* in India, 933.

"Otahitú", Var. Sugar Cane subject to Disease, in Porto Rico, 1239.

*Otiorrhynchus sulcatus*; Parthenogenetic Reproduction; Injuries to Vine in France; Comparison with *O. cribricollis*, *O. ligustici* and *O. turca*, 116.

*Oxycarenus hyalinipennis*: On Cotton in Italian Somaliland, 1184.

*Oxycoccus macrocarpus* (Cranberry): *Fusicoccum putrefaciens* (Blossom Endrot, Stem End Rot or Endrot) in U. S. A., 237. Injurious Insects in U. S. A., 495.

*Oxyuris* (?): On Field Mice, in Italy, 1318.

Oystershell Scale (*Lepidosaphes ulmi*), 247, 495.

**PACHYMERUS QUADRIMACULATUS**: On *Vigna Catjang* in Trinidad, 1182.

*Pachyneuron vindemmiae*: On *Lonchaea aristella* in Italy, 716.

"Paerens blaerefot" (*Euthrips pyri*), 476.

*Paleacrita vernata*: On Apple, Pear and Plum, in Ontario, 247.

*Palaeopus*: *P. costicollis*: On Sweet Potato in Jamaica, 608. *P. dioscureae*: On Tubers of the Yam, in Jamaica, 936. *P. grenadensis* from Grenada and *P. subgranulatus* from St. Vincent, 609.

Palm: *Pseudococcus nipae* in S. Africa, 244. *Aspidiotus cyanophylli*, *A. latniae*, *Chionaspis dentilobis*, *Ch. substriata*, *Chrysomphalus dictyospermi*, and *Ichneaspis longirostris*, In Uganda 243.

Panama: *Aleyrodidae*, 933. *Ptychodes trilineatus*; On Fig, 248.

Pandanus: *Aspidiotus destructor* on

Gold Coast, 242, and in Uganda, 242, 243.

*Panicum*: *P. barbinode*: *Tomaspis varia*, in Grenada, 939. *P. colonum*: Farm Weed in Sindh. (India), 484. *P. latifolium* attacked by *Asterina* (*Asterella*) *fumagina*, in Porto Rico, 103. *P. repens*: *Uromyces linearis* in S. China, 350.

*Panolis griseovariegata*: On Forest Trees in Sweden, 718.

*Papaver*: *P. somniferum*; *Macrosporum somniferi* in Govt. of Podolia, (Russia), 349. *Papaver* spp.: *Aphis acetosae* in Egypt, 487.

*Papilio thoantiades*: On Citrus in the Argentine, 1065.

*Paracalocoris colon*: On Apple in Ontario, 247.

"Para Grass" (*Panicum barbinode*), 939.

Paraguay: *Aleyrodidae*, 933.

*Parietaria officinalis*: Reared from *Pyrameis cardui*, in Hérault, 366.

*Parkinsonia aculeata*: *Inghisia chelonoides* in Coimbatore, 242.

*Parlatoria*: In Jamaica: *P. pergandei* and *P. zizyphi*, 244. In S. Africa *P. pergandei*, *P. proteus*, and *P. zizyphi*, 244.

*Parodiella perisporioides*: On *Desmodium triflorum*, in S. China, 350.

"Päroubladloppe" (*Psylla* sp.), 241.

"Parongallinyggan" (*Contarinia pyrivora*), 241.

Parsnip: *Agriotes lineatus* in Sweden, 241. *Cercospora Pastinacae*, *Cylindrosporium Pastinacae*, *Cylindrosporium Pastinacae*, *Erysiphe Polygoni*, *Phyllachora Pastinacae*, *Plasmodium nivea* and *Ramularia Pastinacae* in England, 825.

Parthenogenesis: *Otiorrhynchus sulcatus*, Coleopteron Injurious to Vine, in France, 116.

"Parsnip Canker" or Parsnip Rust,

- (*Pastinaca sativa* = *Peucedanum sativum*), 825.
- "Pascarolo" (Fig): *Lonchaea aristella*, in Italy, 716.
- Paspalum*: *Paspalum* sp.; *Scapteriscus vicinus* 1063, and *Odontia saccharicola* in Porto Rico, 1176. *P. distichum*: *Ustilagopsis deliquescens*, in Argentine, 179.
- Passer domesticus*, in Sweden, 241.
- Passiflora*: *Aleuroplatus* (*Aleuroplatus*) *oculirenitiformis* in Brazil, 933.
- Pulvinaria jacksoni* in Brit. E. Africa, 242.
- Pastinaca sativa* (= *Peucedanum sativum*): Diseases of Parsnips in England 825.
- Patents, Review of: Control of Diseases and Pests of Plants, 90, 210, 337, 458, 566, 682, 809, 899, 1030, 1155, 1277, 1406.
- "Patte d'oe" Red Grape, Var. offering Relative Resistance to Mildew 105.
- Paulownia* sp.: *Valsa Paulowniae* in Japan, 705. *P. tomentosa* *Helicobasidium Tanakae*, in Japan, 705.
- Peach: *Anuraphis persicae* (= *Aphis persicae*), 630. *Aspidiotus cyanophylli* in Uganda, 242. *A. perniciosus*, in Ontario, 247. Bacteriosis, in Piemont (Italy), 925. *Chrysomphalus dictyospermi* in S. Africa, 244. *Conotrachelus nenuphar*, and *Eccoptogaster rugulosus*, in Ontario, 247. *Exoascus deformans*, 630. *E. d.* in Eritrea, 477. *Hyalopterus pruni*, in N. Africa, 487. *Malacosoma americana*, *M. dissitria*, *Sanninoidea exitiosa*, *Sesia pictipes*, *Tmetocera ocellana*, and *Xylina* spp., in Ontario, 247. *Puccinia Pruni-spinosae*, in Eritrea, 477. "Verde-secco" of Fruit Trees in Apulia, (Italy), 597.
- Peach-tree Borer" (*Sanninoidea exitiosa*), 247.
- Peanut: Resistance towards *Sclerotium Rolfsii*, 478. *Septogloeum Arachidis* in Java and Ceylon, 350. *Cercospora personata* in S. China and W. Indies, and Philippines, 350, 587.
- Pear: *Aspidiotus cydoniae*, in Bangalore, 242. *Bacillus amylovorus* 138. In Ontario; *Aspidiotus perniciosus*, *Carpocapsa pomonella*, *Coleophora fletcherella*, *Eccoptogaster rugulosus*, *Eriocampoides limacina*, *Eriophyes pyri*, *Hemerocampa leucostigma*, *Hyphantria cunea*, *Lepidosaphes ulmi*, *Malacosoma americana*, *M. dissitria*, *Psylla pyricola*, *Tmetocera ocellana*, *Tortrix argyrospila*, *Xylina* spp, 247. (Popular Names See "Apple"). *Contarinia pyrivora* and *Sciurus vulgaris*, in Sweden: 241.
- Pear Blight (*Bacillus amylovorus*), 628.
- Pear Leaf Blister Mite (*Eriophyes pyri*), 247.
- Pear Psylla, (*Psylla pyricola*), 247.
- Pear Slug, (*Eriocampoides limacina*), 247.
- Pear, Wild: Damage done by Locusts in Capitanata (Italy), 1311.
- Peas: *Acanthoscelides obtectus*, in Italy, 606. *Autographa californica* in Brit. Columbia, 1062. *Pseudomonas seminum*, in England; Resistant Vars: and Vars liable to attack, 595.
- Pecan (*Carya olivaeformis*): Important Insect Pests and Their Control, in U. S. A. (Pecan Bud Moth (*Proteopteryx bolliana*); P. Cigar Case Bearer (*Coleophora caryae-foliella*); P. Leaf Case Bearer, (*Acrobasis nebulella*); P. Nut Case bearer (*Acrobasis hebesella*), P. Shuckworm, (*Laspeyresia caryana*), P. Weevil, (*Balaninus caryae*), 496. *Nezara viridula* and Kernel Spot (*Coniothyrium caryogenum*) in Georgia, 927.

- Pectinophora gossypiella* (= *Gelechia gossypiella*) (Pink Bollworm): Origin of this Microlepidopteron, Injuries to Cotton, 1309. Spread in Egypt, 1356. See also *Gelechia gossypiella*.
- Pediculoides ventricosus*: On *Acanthoscelides obtectus*, in Italy, 606.
- Pelargonium zonale*: Damage done by Tarring Streets of Milan (Italy), 584.
- Penicillium*: On Field Mice in Italy, 1318.
- Pennsylvania: *Macrosiphum illinoensis*, 367.
- Pennisetum*: *P. purpureum*: *Coccus tenuivalvatus*, in Uganda, 243. *P. spicatum*: *Puccinia purpurea*, in Eritrea, 477.
- Pepper: *Scapteriscus vicinus* (West Indian Mole Cricket), in Porto Rico, 1063.
- Perezia*: *P. legeri*: On Larvae of *Pieris brassicae*, 603. *P. mesnili*, n. sp.: On Larvae of *Pieris brassicae*, in France, 370.
- Peridermium*: *P. occidentale* (= *Cronartium occidentale*) On *Pinus edulis*, in Colorado, and on *P. monophylla* in Arizona, 1428. *P. ribicola*, in New Mexico, 585.
- Perissocentrus argentinae* var *caridei*, in S. Brazil, 714.
- Peronea minuta*: On *Oxycoccus macrocarpus*, in U. S. A., 495.
- Peronoplasmopara*; *P. cannabina* (Hemp Mildew), *P. cubensis* and *P. Celtidis*; Observations in Italy, 107.
- Peronospora*: *P. parasitica*, (Downy Mildew), On Cultivated Cruciferae, in U. S. A. 594. *P. Schleideni*: On Onions in Indiana, 422.
- Perrisia chrysophyllae*, *P. proxima*, *P. verrucosa*: On *Olea chrysophylla*, in Eritrea, 945.
- Peru: Weevils on Irish Potato Tubers, 936.
- Pewcedanum sativum* (= *Pastinaca sativa*) Parsnip Canker or Rust), in England, 825.
- Pezomachus instabilis*: Nat. Enemy of *Coleophora puscidinella*, in Sweden, 615.
- Phacidium Gaultheriae*: On *Gaultheria Shallon*, Vanouwer Island, 103.
- Phanerogams, 11piiphytic: On Cacao, in State of Bahia (Brazil), 493.
- Phaseolus*: *P. multiflorus*: *Acanthoscelides obtectus*, Distribution, and Morphological and Biological Description, 606. *Ph. vulgaris*, Disinfection of Dwarf Beans infested with *Acanthoscelides obtectus* and *Spermophagus subjasciatus*, 605; *A. obtectus* in Italy, 606. *Pseudococcus virgatus*: On French Beans on Gold Coast, 242.
- Pheidole*: *P. pallidula*, in Hérault, 366. *P. sp.* associated with *Aphis pheidole*, in Rhodesia.
- Phenacoccus insolitus*: On Aubergine, in Madras, 242.
- Philippines: *Aleyrodidae*, 933. *Casca luzonica*, Endophagous parasite of *Schizaspis lobata*; On *Ficus nota* in Los Bânas (Luçon Isle), 1060. *Cylas turcipennis*, On Sweet Potato, at Bay Laguna Prov., 936. Cucumber, (No. 37.700) introduced from Scharuapur (India), Resistant to Insect Attacks, 138. Fungi, 587, 706. Injurious Insects and Diseases of Sweet Potato ("Canote"), 864. *Leucaena glauca*: Used to Control *Imperata arundinacea* ("il-luk"), 1123, and *I. exaltata* (Cogon Grass), 53.
- Phleum pratense*: Resistance to *Sclerotinia Trifoliorum*, 519. *Phleum* spp. *Amaurosoma* (*Cleigastra*) *armillatum* and *A. flavipes*, in Sweden, 241.
- Phloeosinus*: *Ph. cristatus*: On *Abies nobilis*, *Chamaecyparis nootkatensis* and *Picea Engelmanni*, *Ph. den-*

- tatus*: On *Chamaecyparis nootkatensis*; *Ph. punctatus*; On *Chamaecyparis Lawsoniana*, *C. nootkatensis*, *Juniperus occidentalis*, *Libocedrus decurrens*, *Thuja plicata*, in Oregon, 114. *Ph. thuyae*, parasitised by *Scleroderma domesticum* in Hérault, 366.
- Phobocampa* sp.: Nat. Enemy of *Coleophora fuscenedella*, in Sweden, 615.
- Phoeni*: *P. abyssinica* and *P. dactylifera*; *Graphiola Phoenicis*, in Eritrea, 477. *Phoenix* sp.: *Graphiola Phoenicis* in Eritrea, 477; Observations on Damage done by Tarring Streets of Milan (Italy), 584.
- Phoma*: *Ph. Baldraii*; On *Euphorbia Turcath*, 477. *Ph. destructiva*, On Tomato in Tunis, 1306. *Ph. lingam*: (Black Leg) On Cultivated Cruciferae, in U. S. A. 594.
- Phora fasciata*: On *Coccinella septempunctata*, in France, 119.
- Phorbia ceparum*: On Onions in Indiana (U. S. A.) 422.
- Phorocera saundersi*: Nat. Enemy of *Autographa californica*, in Brit. Columbia, 1062.
- Phthorimaea operculella*: On Potatoes in California and Indiana, 1183.
- Phyllachora*: *P. Coicis*: On *Coix Lacryma-Jobi*: and *P. Cynodontis*: On *Cynodon Dactylon*. in S. China, 350. *P. Heraclei*: On *Heracleum Sphondilium* (Cow Parsnip), in England, 825. *P. orbicula*: On *Bambusa Blumeana*, in S. China, 350. *P. Pastinacae*: On Parsnip in England, 825. *P. Roystoneae*: On *Roystonea regia* in Cuba, 482.
- Phyllactinia suffulta*: On Common Oak, in Spain, 601.
- Phyllanthus myrtifolius*: *Dialeurodes (Dialeuronomada) dissimilis*, in India, 933.
- Phyllobius* sp.: On Fruit Trees in Sweden 241.
- Phylloscelis atra* (Cranberry Toad-bug), On *Oxycoccus macrocarpus* in U. S. A., 495.
- Phyllosticta*: *P. cicerina*, 1177. *P. citricola* and *P. curvatispora* (Kasshoku-komaru-boshibyō); On Citrus, in Japan, 102. *P. (Phoma) kuwacola*: On *Morus alba*, in Japan, 705. *P. Rabiei*: On Chick Pea, Specific Agent of Rabbia", in Italy, 1177.
- Phyllotreta* sp.; On Cabbages and Turnips in Sweden, 241.
- Phylloxera*: Direct Vine Bearers, and Resistant Qualities, in France, 1250. in State of N. York, 425. Selection of Plants Resistant to Diseases, and Animal Pests. Experiments in Germany, and Results, in U. S. A., France, India, Australia, N. Zealand, E. Indies, and Russia, 519.
- Phylloxera caryaecaulis* (Hickory Phylloxera): On Pecan, in U. S. A., 496.
- Phymata noualhieri*: On *Melia sempervivens* Nat, Enemy of *Musca domestica*, In Mexico, 722.
- Physokermes abietis*: On Spruce in England, 485.
- Physopus*: *P. robustus* on Leguminosae in Sweden, 241. *P. rubrocinctus* On Cacao, in State of Bahia (Brazil), 493.
- Physothrips*: *P. funtumiae*; On *Funtumia elastica* in S. Nigeria and Uganda, 937. *P. kellyanus*: On *Acokanthera spectabilis*, *Helianthus* (?) and *Hypochoeris radicata*, in Australia, 937. *P. lefroyi* and *P. setiventris*: On Tea in India, 941. *P. marshalli*: On Potato etc. in Gold Coast, 937.
- Phytalus georgianus*: On *Oxycoccus macrocarpus*, in U. S. A., 495.
- Phytoecia cylindrica*: On Carrots in Sweden 121.
- Phytopathology: Observatory of Turin (Italy); Service of "Preventive

- Detecction against Vine Mildew, 925.
- Phytophthora*: Resistant Vars of Potato, 519. *P. Faberi*: On Cao in State of Bahia (Brazil), 493. *P. infestans*; "New Era" Var. Potato immune from Potato Blight, introduced into U. S. A. 138.
- Pica pica* ("Skatan") in Sweden, 241.
- Picea*: In Oregon (U. S. A.); *P. Engelmanni*: *Dendroctonus engelmanni*, *Eccoptogaster unispinosus*, *Ips caelatus* var. and *Phloeosinus cristatus*, 114. *P. sitchensis*: *Dendroctonus obesus*, *Dolurgus pumilus*, *Ips interruptus*, *I. concinnus*, and *Pityophthorus puncticollis*, 114. *Picea* sp.: *Pityophthorus nitidulus*, 114.
- Pieris brassicae*: *Perezia legeri*, 603; *Perezia mesnili*, 370; and *Pimpla alternans*, 366; (Parasites on Larvae).
- Pine: *Coccus resinifians*: On Scotch Pine, Cluster Pine and Spruce, 1219. *Evetria buoliana*, Microlepidopteron Injuries in France, 948, 1061. Tumours of Cluster Pine (*Pinus Pinaster*), in France, 600. Use of Bats in Control of Insects, Especially Tortricidae, *Evetria* (*Retinia*) *resinella*, *E. buoliana* and *E. turionana* in France, 1061.
- Pine: *Coccus resinifians*, 1219.
- Pineapple: *Pseudococcus bromeliae* in Uganda, 243.
- Pine Apple Disease: Of Sugar Cane (*Thielaviopsis paradoxa*), 1057.
- Pink Bollworm (*Pectinophora gossypiella*): On Cotton, 1309.
- Pinnaaspis aspidistrae*: In Green houses, S. Africa, 244.
- "Pinoli" Var. Bean subject to *Acanthocelides obtectus*, 606
- "Pifion Bliester Rust" (*Peridermium occidentale*), Pifion Pines, (*Pinus cembroides*, *P. edulis*, *P. monophylla* and *P. quadrifolia*, in Arizona and Colorado, 1428.
- Pinot blanc Chardonnay, P. blanc vrai, P. (Gros) blanc hâtif, P. noir, P. Renevey amélioré and P. noir Saint-Laurent, French Vines Immune to Mildew, 105.
- Pinus*: *P. Armandi*, *P. Ayacahuite*, *P. Bungeana* and *P. Cembra*, Immune to *Evetria buoliana* Attacks, and *P. Balfouriana*, liable to attack, France. *P. cembroides* (Pinon Pine), in Colorado and Arizona, 1428. *P. contorta*: *Conophthorus* sp.; *Dendroctonus monticolae*, *D. valens*, *Gnathotrichus retusus*, *Hylurgops lecontei*, *Ips concinnus*, *I. emarginatus*, *I. radiatus*, *I. interpunctatus*, *Pityophthorus puncticollis* and *Trypodendron ruftarsus*, in Oregon, 114; *E. buoliana* in France, 948. *P. Coulteri*: *E. buoliana*, in France, 948. *P. densiflora*: *Cercospora Pini-densiflorae*, in Japan, 705. *P. edulis*: *Peridermium occidentale*, in Colorado, 1428. *P. excelsa*; Immune to *E. buoliana*, in France, 948. *P. halepensis*: *Myrmecophila acervorum* on Bark with *Crematogaster scutellaris*, in Hérault, 366. *P. Jeffreyi*: *E. buoliana* in France and *P. koraiensis*, immune, 948. *P. Lambertiana*: *Dendroctonus monticolae*, in Oregon, 114. *P. Laricio*, and *P. Laricio*, var. *austriaca*, 948. *P. leiophylla*: *E. buoliana*, in France, 948. *P. monophylla*: *E. buoliana*, in France, 948, and *Peridermium occidentale* in Arizona, 1428, *P. monticola* and *Hylurgops rugipennis* in Oregon, 114. *P. monticola*: Immune to *E. buoliana* in France, 948. *P. muricata* and *P. Pinaster*; *E. buoliana* in France, 948 and *P. parviflora*, *P. pentaphylla*, *P. l'euze*, Immune, 948. *P. Pinaster*; Tumours of Cluster Pine in France, 948. *P. ponderosa*: *Dendroctonus*

- brevicornis*, *D. monticolae*, *D. valens*, *Gnathotrichus retusus*, *Hylurgops subcostulatus*, *H. lecontei*, *Ips emarginatus*, *Ips* n. sp. *H. latidens* *I. oregona*, *I. radiata*, *Orthotomicus ornatus*, *Pityogenes carinulatus* in Oregon, 114. *E. buoliana*, in France, 948. *P. ponderosa* var. *Malletii*: *E. buoliana* in France, 948. *P. quadrifolia*, 1428. *P. rigida*, *P. Strubus*, *P. sylvestris*, *P. sylvestris* var. *rigensis*, Immune, and *P. Sabini*, *P. Taeda*, *P. Thunbergii*, *P. uncinata* *P. Wilsoni*, *P. yunnanensis*, At-tacked by *Evetria buoliana*, in France 948. *P. yunnanensis*: *Ips confusus*, in Oregon, 114, 948. *Pinus* sp.; *Pityophthorus nitidulus* and *Pit., confertus*, in Oregon, 114.
- Piper Beetle: *Aleurocanthus nubilans* in India, 933. *P. nigrum* (?): *Aleurocanthus piperis* in India, 933. *P. retrofractum* and *Piper* sp.: *Actinodothus Piperis* in the Philippines, 587.
- "Piroli" (Bean): *Acanthoscelides oblectus*, 606.
- Pissulocystia oxycarenidis*: Nat. Enemy of *Oxycarenus hyalinipennis*, in Italian Somaliland, 1184.
- Pistachio: *Megastimus ballestrerii* (= *Trogocarpus ballestrerii*), In Sicily, 831.
- Pistol Case-bearer (*Coleophora malivorella*), 247.
- Pistacia Terebinthus* and *P. vera*, 831.
- Pisum sativum*: *Acanthoscelides oblectus*, in Italy, 606. *Pseudomonas seminum*, in England, 595.
- Pittosporum undulatum*: *Helicobasidium Tanakae*, in Japan, 705.
- Pitymys savit*: *Bacterium murisepticum*, Specific Agent, of this Infections Disease of Field mice, in Apulia, (Italy), 1187. Biological Control, in Capitanata, (Italy), 1318. Preparation of Active Virus against Field Mice, and Method, of Applying it in Infected Fields, 1316. Susceptibility in Apulia to certain Micro-organisms used to Control these Rodents in the Fields 1317.
- Pityogenes*: *P. carinulatus*: On *Pinus ponderosa* in Oregon, 114. *P. chalcographus* 718: *Pityogenes* spp. on Forest Trees in Sweden, 241.
- Pityoktaines jasperi*: On *Abies grandis* and *A. lasiocarpa*, in Oregon, 114.
- Pityophthorus*: *P. confertus*, Reared, from Pine Cones, *P. confinus*, *P. nitidulus*; On *Pinus Picea* and *Pseudotsuga*, *P. pubipennis*; On *Fraxinus oregona* and *Quercus Geryana*, *P. puncticollis*; On *Picea sutchensis* and *Pinus contorta*, and *Pityophthorus* n. sp.; On *Abies grandis*, and *A. nobilis*, in Oregon, 114.
- Plagia americana*: On *Autographa californica*, in Brit. Columbia, 1062.

Sugar Cane; Diseases of, 1057; Resistant Vars., 1239, *Odontha Sacchari* and *O. saccharicola*, 1176. "Otahitu" or "Caña blanca", Var. attacked by Disease, 1239. Sweet Potatoes; *Cylas formicarius*, and Control Methods, 1434. *Euscepes batatae* in Mayaguez, 936.
- Portuguese Congo: *Aspidoproctus armatus*; On Tree of Unknown Species, San Salvador, 242.
- Potato: *Agriolimax agrestis* and *Agriotes mancus* (?) in N. York State, 943. *Agriotes lineatus*, in Sweden, 241. *Autographa californica*, in Brit. Columbia, 1062. "Black Leg"; Caused by *Bacillus atrosep-ticus* in Lancashire: England, and by *B. melanogenes* in Ireland, 358. *Chrysophlyctis endobiotica*, Resistant Vars. in U. S. A., 519. *Fusarium* spp. Resistant Vars. in Germany, 519. *Limax agrestis*, in Norway, 476. Mite Disease, in Hawaii, 1314. *Oospora Scabies* (Po-

- tato Scab), Use of Mercuric Chloride, in U. S. A., 491. *Phora lasciatula* (Parasite of *Coccinella septempunctata*), in France, 119. *Physothrips marshalli*: On Gold Coast, 937. *Phthorimaea operculella*. In Indiana, (U. S. A.), 1183. *Phytophthora infestans*, In Europe, 519; New Era Var. (from N. Zealand) introduced into U. S. A., Immune, 138. *Scapteriscus vicinus*, (West Indian Mole Cricket), in Porto Rico, 1063. *Synchytrium endobioticum* in Norway, 476. *Tylenchus penetrans*, New Nematode Parasite in Michigan. 491. Weevils; On Irish Potato Tubers, in Argentina, Bolivia, Chile, and Peru, 936.
- Potato Scab (*Oospora Scabies*), 491.
- Potato Tuber Moth (*Phthorimaea operculella*), 1183.
- "Potet kraeft" (*Synchytrium endobioticum*), 476.
- Powdery Mildew: On Cruciferae (*Erysiphe Polygoni*), 594.
- "Premici" (Large White Bean), in Tuscany; *Acanthoscelides obtectus* (Bean Weevil), 606.
- Premnotrypes solani*: On Irish Potato Tubers, in Peru, 936.
- Primula sinensis*: Damage done by Tarring Streets of Milan, (Italy), 584.
- Princes Island: White Ants, 609.
- Pristiphora appendiculata*; On Gooseberry, in Sweden, 241.
- Privet: *Siphocoryne ligustri*, in Sweden, 241.
- Procryphalus aceris*, On *Acer macrophyllum*, in Oregon, 114.
- Prospaltella fasciata*: Nat. Enemy of *Chrysomphalus dictyospermi* living on *Sansevieria arborescens*, in Italy, 118.
- Proteopteryx bolliana* (Bud Moth): On Pecan, in U. S. A., 496.
- Protopulvinaria pyrifomis*: in S. Africa, 244.
- Protozoa: On Field Mice, in Italy, 1318.
- Prunus*: *Corythuca spinulosa*; On *P. serotina*, in New Jersey, 717. *Helicobasidium Tanakae*: On *P. Armeniaca* var. *Ansu*, *P. donarium*, (= *P. paniculata*), *P. Mume*, *P. salicina*, in Japan. *Hyalopterus pruni*, *Hyal. arundinis*, *Hyal. phragmiticola*: On *Prunus* spp, in Egypt, 487. *Olethreutes variegana* on *P. Avium*, *P. Cerasus*, *P. insititia*, in Italy, 611. *Puccinia heterospora*; On *P. Persica*, in S. China, 350. *Septobasidium Acaciae*; On *P. Persica* and *P. salicina*, in Formosa, 705.
- Pseudaonidia*: *P. barkiaeae*; On *Barkiaeae* sp. in Uganda, 243. *P. trilobitiformis*; On Mango and Oleander, in Uganda, 243; On *Nephelium Lit-chi*, in S. Africa, 244.
- Pseudaphelinus caridei*: Nat. Enemy of *Pulvinaria flavescens*, *P. minuta* and *P. platensis* in Argentina, 1308.
- Pseudococcus*: In Africa Brit. E., *Ps. citri*, on *Citrus*, 242. In Africa S., *Ps. adonidum*, on Pot Plants; *Ps. aurilanatus*, *Ps. bromeliae*, *Ps. burnerae*; *Ps. citri*, On *Citrus*, 244. *Ps. capensis*, on Vines, 244. *Ps. citri*, var. *colearum*, on *Coleus*, 244. *Ps. capensis* on Vines, *Ps. flamentosus* on *Citrus* and *Grevillea*, *Ps. fragilis* on *Citrus*, *Ps. nypae*, on Palms; *Ps. sacchari*, *Ps. virgatus*, 244. *Ps. hymenocleae* on, Unknown Plant in Transvaal, 242. On Gold Coast, *Ps. virgatus*; On *Colocasia*, French Bean, *Jatropha*, *Curcas* Oleander, "Salonica" (Creeper), 242. In Guiana Brit: *P. sacchari* On Sugar Cane, 242. In England, *Ps. longispinus*; On Banana; *Ps. longispinus*, var. *latipes* n. var.; On Fuchsia and Cacti, *P. newsteadii*, on *Fagus sylvatica*, and *P. walkeri*, 485. In Madras, *P. sacchari*; On Rice 242. In Nigeria S., *Ps. virgatus*, On Cacao, 242. In Uganda: *Ps. brome-*

"Råkan" (*Corvus frugilegus*), 241.  
*Ramularia*: *R. Clematidis*: On *Clematis ligusticifolia*, in Montana, 103.  
*R. Pastinacae*: On Parsnip in England, 825.  
 "Randiga ädesknäpparen" (*Agriotes lineatus*), 241.  
*Raphanus sativus*: *Siphocoryne* (*Aphis*) *pseudobrassicæ*, in U. S. A. and S. Africa, 487.  
 "Rapssugaren" (*Eurydema oleracea*, 241.  
 Rats. White: *Bacterium typhimurium* (?) in Rome, 1318.  
 "Red Astrachan" Var. Apple Attacked by *Rhagoletis pomonella*, in Brit. Columbia, 122.  
 "Red Leaf Spot" of Sugar Cane (*Eriosphæria Sacchari*), 1057.  
 "Red Rot of Leaf Sheath" of Sugar Cane, (*Sclerotium Rolfsii*), 1057.  
 Red Shouldered Shot-hole Borer [*Sinoxylon*] *Xylobiops basilaris*, on Pecan, 496.  
 Red Spider (*Tetranychus pilosus* = *T. mytilaspidis*), 247.  
 Red Spot of Leaf Sheath, of Sugar Cane, (*Cercospora vaginæ*), 1057.  
 "Red Striped Fireworm" (*Gelechia trialebamaculella*), 495.  
*Reduviolus jerus*: On *Blissus leucopterus* in Illinois, 1431.  
*Reseda lutea*: *Rhytidoderes plicatus*, in Hérault, 602.  
 Resistance of Plants: *AMYGDALUS* spp. and *A. tangutica*: To Drought and Cold in Prov. Kansu, China, 1068.  
 APPLES: Methods of Selection of Vars: To *Bortyitis cinerea*, 519; † Vars: introduced into U. S. A. to Woolly Aphis (*Eriosoma lanigera*), 628. ASPARAGUS Vars: To *Puccinia Asparagi*, in U. S. A., 285, 519. BARLEY; Danish 2-rowed and 6-rowed; (introduced into U. S. A.); To *Ustilago Hordei*, *U. nuda*, and *Septoria graminum*, 138. CACAO (African): To *Ephestia elutella*, 519.

CEREALS: To Cold, Lodging and Rust in Sweden, 143; Relation of Density of Cell Sap to Winter Hardiness in Small Grains, in U. S. A. 1217. CHESTNUT: (Hybrids) To *Dia-porthe parasitica* (= *Endothia parasitica*), in U. S. A., 286; 'Kwei-li-tzu' (Chinese Chestnut) introduced into U. S. A.: To Bark Disease, 138. COFFEE (Var. *Coffea liberica* replacing *C. arabica*) and Hybrids from these Crosses.: To *Hemileia vastatrix*, in E. Indies, 519. COTTON: To *Saissetia nigra*, (Black Scale), In St. Vincent; 117: CUCUMBER: (No. 37700). Introduced from India, To Insect Attacks, In the Philippines. 138. *FESTUCA ELATIOR* (Meadow Fescue), Danish Selection introduced into U. S. A.: To Rust (*Puccinia*), 138. *FESTUCA PRATENSIS*, *PHLEUM PRATENSE* and *POA SEROTINA*: To *Sclerotinia Trifoliorum*, 519. FLAX. Var. To Flax Wilt (*Fusarium Linii*), in U. S. A.; 283. Gooseberry: in U. S. A.: To *Puccinia Ribis*, 519. HOP (*Humulus Lupulus*). To Mildew (*Sphaerotheca Humuli*), in England, 232. MAIZE: To Smut (*Ustilago Zeæ*), Selection in U. S. A., 1099. OAK: Vars: *Quercus palustris*, and *Q. rubra* var. *americana*: To *Phyllactinia suffulla*, in Spain, 601.; OATS: "Ruakura Rust Resistant", in N. Zealand, 519. PEANUTS: To *Sclerotium Rolfsii*, in Virginia, 478. PEA Vars: Sutton's Improved Petit Pois; To *Pseudomonas seminum*, in England, 595. PEAR; Var. Kieffer (Parent Probably *Pyrus ovoidea*), and *P. phaeocarpa*, Vars; imported into U. S. A.; To *Bacillus amylovorus*, 628. PLANTS Resistant to Diseases, Animal Pests and Adverse Meteorological Conditions, in Germany, United States, France, India, Australia, New Zealand, East Indies, and Russia. 519. POTATO.

"New Era", New Zealand Var. introduced into U. S. A.; To Blight (*Phytophthora infestans*), 138. Selection in Norway: To "Lodging", 855. SUNFLOWER; Russian Var.  $\times$  Californian var: To *Homoeosoma nebulellu*, in Russia, 519. SPELT, W. European Types compared with Turkestan and Samara Vars; To Brown Rust (*Puccinia triticina*), 519. STRAWBERRY Var. Minnesota No. 1017, To Cryptogamic Diseases, in U. S. A., 298. SUGAR BEET; To *Heterodera Schachtii*, Trials in Germany, 519. SUGAR CANE, Vars: B-4596, B-3412, D-117, Caledonia Amarilla: To Disease Generally, in Porto Rico, 1239; Tjerbon  $\times$  Tschun in E. Indies: To Rust, 519. SWEDE; Selection of Vars: in Denmark; To *Plasmodiophora Brassicae*, 282. SWEET MAIZE; Vars: To Maize Earworm (*Chloridea obsoleta*), in U. S. A. 279. Tobacco, Type in Germany: To *Bacillus maculicola*, 519. VINE: American Vine Scion on European Stock; To Phylloxera; In Italy, 633. Chasselas  $\times$  Berlandieri 41 B. Vine: To Bramble Leaf Disease, in Sicily, 873. "Couderc" Vars. Old Hybrids; No. in S. France, 503; 770 To Black Rot, and No. 7120; To Oidium (almost immune) Newer Hybrids; Nos. 106-46, To Mildew, 519, 770. No. 235-120, 272-60, To Mildew etc., 519. Direct Bearers, at Hérault; To Chlorosis, Mildew, Phylloxera and Scorching, 1250. Effect of Pruning on Grafted Vines, Relative to Mildew, 1251. French Vines; To Mildew, 105. Hybrid Bearers in France in 1917: To "Anthracnose", Mildew, Oidium, Brown Rot and Black Rot, Black Rust, 303. Hybrid Maurice Baco 22 A (Folle Blanche  $\times$  Noah), in France; To *Botrytis cinerea*,

519. Hybrids, of *Vitis europaea* and *V. Labrusca*, in France, Mildew, Oidium and Black Rot, 519. Influence of American Vine Scion on European Stock, with regard to Phylloxera, 630. Jurie No. 580; (high yield) in France, To Disease Generally, 770; To Mildew, 519. Malègue, No. 829-6; To Mildew; in France, 770, and Nos. 2094-3, 2183-3, 829-6, 474-5, 57-1, 1157-15, 1647-8, 1897-12, To Mildew, 519. Pinot (Gros blanc hâtif); To Oidium; and Pinot (Noir Saint-Laurent); To Black Rot, 105. Resistance to Cold, Classification of Vars: in Kentucky, 384. "Seibel" Vars: Old Hybrids, Nos. 2 and 63 (Large Producers); To Mildew; Newer Hybrids, No. 4121; To Disease Generally: New Hybrids, Nos 4762 and 4995; To Mildew 770. Seibel. Nos. 793-880 - 2653 - 4645 - 4991, 873 - 1082, 4121, 2857, 4464; To Mildew, etc., 519, in France. Stock imported from France into Sicily; To Chlorosis, 651. Trials in Germany to obtain Vars: Resistant to *Phylloxera*, 519. Vars: To Black Rot (*Guignardia Bidwellii*); in U. S. A., 519. *Vigna Catjang*: Cross between Iron Var, and Black and Whippoorwill Vars: To *Fusarium tracheiphilum* and *Heterodera radiculicola*; in U. S. A., 519. VIRGINIA CREEPER (*Vitis hederacea*): To Vine Mildew (*Uncinula necator*), 105. WATER MELON; Var: Conqueror", in U. S. A.; To *Fusarium nivium*, 519. WHEAT: To *Cicadula sexnotata*, in Sweden, 1313; Manitoba Var.; To Drought and Rust, 34; and to Fungus Diseases, (including Smut). Comparison with "Japhet" and "Bon Fermier" (Alternative Vars.) and "Aurore" and "Saumier de Printemps" (Spring Vars.), 1051;

- Spring Var: Schlanstedter: To *Ustilago Tritici*, in Germany, 519; Spring Vars: To *Fusarium culmorum*, in Sweden, 1297. Different Vars: To Cold in France, 157; To Rust, *Tilletia laevis* and *T. tritici*, in India, Australia and N. Zealand, 519; To Rust and Lodging in India, 854.
- Réunion: Pests observed on Tobacco from R. Grown in Mauritius, 942.
- Rhabdophaga oleiperda*: On *Olea chrysophylla* in Eritrea, 945.
- Rhabdopterus picipes*: On *Oxyccus macrocarpus*, in U. S. A., 495.
- Rhagoletis*: *R. cingulata*, *R. fausta*, in Ontario, 247. *R. pomonella* (= *R. zephyria*) (Apple Maggot or Railroad Worm) in Brit. Columbia, 122; in Ontario, 247.
- Rhamnus Alaternus*: *Anthaxia manca*, *Hylesinus vittatus*, and *Scolytus multistriatus*, in Hérault, 602.
- Rhigopsidius tucumanus*: On Irish Potato Tubers in Argentine, Peru, Bolivia and Chile, 936.
- Rhinolophus*: Gen: Bats, 1061.
- Rhizobius lophantae* and *Rhiz. ventralis*: On *Chrysomphalus dictyospermi*, 118.
- Rhizopertha dominica*: Pest in Stored Food Stuffs in Java, 1438.
- Rhizophora Mangle*: Host of *Clytus devastator*, Cuba and Florida, 1437.
- Rhodesia: *Aspidiotus (Chrysomphalus) auranti* in the South, 242. *Tagetes minuta*, Troublesome Weed, 932. Coccida, 242.
- Rhododendron: *Autographa californica*; In Brit. Columbia, 1062. *Stephanitis rhododendri*; In France, 944.
- Rhogas autographae*: Nat: Enemy of *Autographa californica* in Brit. Columbia, 1062.
- Rhopalosiphum*: *R. dianthi*: With *Aphis brassicae*; On *Brassica oleracea* and *B. oleracea bullata major*, in Egypt, 487. *R. ribis*; On *Ribes* sp. in S. E. Russia, 1180. *R. lactucae*; On Gooseberries, and Red Currant in Sweden, 241; On *Ribes* sp.: in S. E. Russia, 1180.
- Rhopobola vacciniana*: (Blackhead Fireworm) On *Oxyccus macrocarpus* in U. S. A., 495.
- Rhynchites bacchus* (with *Rhyn. auratus*, *Rhyn. giganteus* and *Rhyn. ruber*): On Apples, Apricots and Plums, in Sicily, 374.
- Rhytidoderes phlicatus*: On Calbage, *Diplotaxis tenuifolia*, and *Reseda lutea*, in Hérault, 602.
- Ribes*: *R. americanum*, *R. coloradense*, *R. Giraulti*, *R. glundulosum*, *R. malvaceum*, *R. nigrum*, *R. odoratum*, *R. sanguineum*, *Ribes* sp.: Attacked by *Cronartium occidentale* in Colorado and Arizona, 1428. *R. aureum*: *Coleosporium ribicola* in New Mexico, 585, and *Cronartium occidentale* in Colorado, Arizona and Kansas, 1428. *R. bracteosum*: *Gloeosporium Bartholomaei* and *Marssonina bracteosa* in State of Washington, 103. *R. Grosularia*: *Helicobasidium Tanakae*, in Japan, 705. *R. inebrians*, *R. longifolium* (longiflorum?), *R. mescaleum* and *R. Wolfi* in New Mexico, 585. *Ribes* sp.: *Rhopalosiphum ribis*; in S. E. Russia, 1180.
- "Ribier" ("Black Morocco"): Var. of Vine injured by *Diclyothrips aegyptiacus*, in Cyrenaica, 715.
- Rice: Diseases and Pests in Brit. Empire, 254. *Leptocorisa varicornis* in Assam, (India), 604. *Pseudococcus sacchari*, in Madras, 242. *Scapteriscus vicinus* (West Indian Mole injurious Cricket), to Crops in Porto Rico, 1063. "Wild" Rice; Transplanting in Control of Infested Area in Italy ("Riso erodo" or "riso selvatico"), 161.
- Rice Bug, (*Leptocorisa varicornis*), 604.

- Ricefields : Carp Breeding in Transplanted Rice Fields, Destruction of Weeds by Eating seeds, at Vercelli (Italy), 78. Control of Weeds in Ricefields by Rolling, (Italy), 1106.
- Ricinus* (Castor Oil Plant) : *R. communis* : *Bacillus Solanacearum* Injuries in U. S. A. (Florida and Georgia), 1055. *Cladosporium densus* in Campania (Italy), 1173. *R. communis*  $\beta$  *africanus* : *Melampsora Ricini* in Eritrea, 477.
- Rind Fungus (*Coniothyrium melasporum* and *Darlucella melaspora* (= *Melanconium Sacchari*), 1057.
- "Ringspinnaren" (*Malacosoma neustria*), 241.
- Ripersia halophila* : On Roots of Grapes, in England, 485.
- "Riso crodo" or "Riso selvatico" (Wild Rice) in Italy, 161.
- Robinia : *Signiphora merceti* obtained from *Hemiberlesia camelliae* on Plant from Lucca (Italy), 118.
- "Rönnbärsmalen" (*Argyresthia conjugella*), 241.
- Root Disease of Sugar Cane, (*Marasmius stenophyllus*, *M. Sacchari*), 1057.
- Root Knot (*Heterodera radiculicola*), 238, 594.
- Root Rot, (Non Bacterial Origen) of Cultivated Cruciferae, 594.
- Root Rot : (*Thielavia basicola*). Broad Leaf Burley and Irish Gold Tobacco Vars : very susceptible, in Ireland, in 1916, 49.
- Rose : *Actinonema Rosae* (Rose Blotch Fungus), Life History, and Vars : Attacked, in Great Britain, 1296. *Aleurocanthus spiniferus* in Java, 933. *Aspidiotus cydoniae*, in Uganda, and *Aspid. camelliae* in S. Africa, 242. *Autographa californica*, in Brit. Columbia, 1062. *Chrysomphalus dictyospermi*, in Uganda. 243 ; and in S. Africa, 244.
- Rose Bay : *Bacillus oleae*, in Eritrea, 477. *Chilocorus bipustulatus*, Destroyer of *Chrysomphalus dictyospermi* found on Leaves.
- Rosellinia necatrix* : On Fruit Trees in Apulia (Italy), 597.
- Rosy Aphis (*Aphis [sorbi] malifoliae*), on Apples, in Ontario, 247.
- Rosy Aphis Stigmatose, see Apple Spot Diseases, 1048.
- Rot, Grey : "Maurice Baco" Subject o Disease. 770 Resistant Hybrid Bearers, in France, 303, 770.
- Round-headed Apple Tree Borer (*Saperda candida*), in Ontario, 247.
- Roystonea regia (Royal Palm) : *Phyllochora Roystoneae* in Cuba, 482.
- "Ruakura Rust Resistant", Oat var. in N. Zealand, 519.
- Rubus* : *Autographa californica*, in U. S. A., 1062.
- Rumex* spp. : *Aphis acetosae*, in Egypt 487. *Autographa californica*, in U. S. A., 1062. *R. Acetosella* and *R. crispus*, Amongst Cereals in Montana, 639.
- "Russa" Eruption behind Ears of Field Mice in Italy, 1318
- Russia : Aphides collected on Stepes in S. E. near Odessa, and near Galatz, 1180. *Hyperecteina polyphylla* ; Dipterous Parasite on Lamellicorn Beetle *Polyphylla fullo*, and Saprophagous Dipteran, Gen. *Sarcophaga*, on the Dead Beetle, 371. Parasite Fungi collected in Govt. of Podolia, 1915, 349. Sunflower Vars. Resistant to *Homoeosoma nebulella*, at Saratov, 519.
- Rust : Brown Rust (*Puccinia triticina*) : Spelt Vars. (*Triticum Spelta*) from Turkestan and Samara very Subject to Disease, 519. Cereals, Rust of, particularly Black Rust of Wheat, (Australian Interstate Conference of Agricultural Scientists), 1076. RESISTANT VARIETIES : Aspa-

- ragus; Selection of Resistant Strains, in Massachusetts, U. S. A., 285. Cereals in Sweden, 143. *Festuca elatior*, Meadow Fescue (37, 710) Danish Selection introduced into U. S. A., 138. Wheat: Vars: "Bore" and "Lignée" 0728. Comparative Resistance to Disease, 519. Manitoba Vars. Resistant Qualities, 34. Resistant Vars: in India, Australia and N. Zealand, Oat var: "Ruakura Rust Resistant" in N. Zealand, 519. Selection in India, Comparison between Old and New Vars, 854.
- Rye: *Agriotes lineatus*, in Sweden, 241.
- SACCHARUM OFFICINARUM: *Aleurolobus borodensis*, in India, 933. *Odon-tia Sacchari* and *O. saccharicola* in Porto Rico and Cuba, 1176.
- "Sadesbroddflyet", *Agrotis segetum*, 241.
- Saint Kitt: *Euscepes batatae*: on Sweet Potato, 939.
- Saint Vincent: *Euscepes batatae*: On Sweet Potato, 936; *Paleopus subgranulatus*, 608. *Saissetia nigra*, 117.
- Saissetia*: *S. hemisphaerica*: On Coffee and Ferns in Uganda, 243. On Pot Plants, in S. Africa, 244. *S. nigra* (*S. nigrella*); On Coffee, *Ficus*, sp and *Anona muricata*, in Uganda, 243; On *Ficus* spp. only in S. Africa; Cotton, Resistant to Black Scale (*S. n.*) in St. Vincent, 117. *S. oleae*: In Italy, 118, 828; In S. Africa, 244. In Uganda; On *Chlorophora excelsa*, parasitised by *Coccophagus saintebuvei*, 243. *S. subhemisphaerica*: On Coffee in Uganda, 243.
- "Sal" (*Shorea robusta*), in India, 1295.
- Salad Plants: *Agriotes lineatus* in Sweden, 241.
- "Salalé" (*Neotermes gestri*); In São Thomé, 609.
- Salix*: *S. alba*: *Anthaxia aurulenta* in Hérault, 602. *S. Fendleriana*; *Septogloeum Salicis-Fendlerianae* in Idaho, 103. *S. glandulosa* var. *Warburgii*: *Septobasidium Acaciae*, in Japan, 705. *Salix* sp: *Chionaspis* (*Hemichionaspis*) *minor*, in S. Africa, 242; *Helicobasidium Tanakae* in Japan, 705.
- "Salonica" Creeper: *Pseudococcus virgatus* on Gold Coast, 242.
- Salpingogaster nigra*: Nat. Enemy of *Tomaspsis saccharina* in Trinidad, 939.
- Sambucus*. sp.: *Aphis laburni*, in S. E. Russia, 1180.
- Sandalwood, see *Santalum album*.
- San José Scale (*Aspidiotus perniciosus*); On Fruit Trees, Ontario, 247.
- Sanninoidea exitiosa* (Peach-Tree Borer): In Ontario, 247.
- Sansevieria arborescens*: Host of *Chrysomphalus dictyospermi* attacked by *Aspidiotiphagus citrinus* and *Prospaltella fasciata* in Italy, 118.
- Santo Domingo: Diseases of Sugar Cane, 1057.
- Santalum album*: Spike Disease in Mysore (India), 5.
- São Thomé: Insect Parasites; — On Cacao; *Aspidiotus palmarum*, *As. trilobitiformis*, *Microcerotermes parvus*, subsp. *theobromae*, *Neotermes gestri*; On *Carica Papaya*; *As. articulatus*, *As. palmarum*; On Coffee; *As. articulatus*, *Capnodium Coffeae* (?); *Cephalosporium Lecanii* (Nat. Enemy of *Lecanium viride*); *Orthezia insignis*; On *Ficus*; *As. articulatus* and *As. palmarum*, 619.
- Saperda candida*: (Round-headed Apple Tree Borer), in Ontario, 247.
- Sapium mannianum*: *Aulacaspis chionaspis* and *Chionaspis dentulobis*, in Uganda, 243.
- Saponaria Vaccaria*: On Cereals in Montana, 639.
- "Sarang" (*Tribulus terrestris*), 484.

- Sarcobatus vermiculatus*: *Septoria Sarcobati*, in Montana, 103.
- Sarcophaga*: *Sarcophagous Dipteron* on Dead Lamellicorn Beetle (*Polyphylla fullo*), in Russia,
- Sarcoystis pitymyi*: On Field Mice in Italy, 1318.
- Sargatus websteri*: Nat. Enemy of *Autographa californica* in Brit. Columbia, 1062.
- Saskatchewan: *Autographa californica*, 1062.
- "Savri" (*Panicum colonum*), 484.
- Scapteriscus*: *S. vicinus*, (West Indian Mole Cricket), injurious to Crops in Porto Rico, and *S. didactylus*, 1063.
- "Scarabee" of Sweet Potato (*Euscepes batatae*), 608, 936.
- Schedius kuwanae*: On *Porthetria dispar*, in Spain, 1432.
- Schinus dependens*: *Pulvinaria minuta* in Argentina, 1308.
- Schistocerca alutacea*: On *Oxyccus macrocarpus*, in U. S. A., 495.
- Schizaspis lobata*: Parasitised by *Casca luzonica*, in the Philippines, 1060.
- Schizoneura*: *S. lanigera* (= *Myzoxylus laniger*); On Apple, in Italy, 630.
- S. ulmi*; On Elms, in Odessa, 1180.
- Schizonotus decolor*: *Septogloeum Schizonoti*, in Vancouver Island, 103.
- Schizophyllum alneum*: On Sugar Cane in Tropical, Sub-Tropical America, especially West Indies, 1057.
- "Schlanstedter", Spring Wheat Var: resistant to *Ustilago Tritici* in Germany, 519.
- "Schorikrankheit" (*Chrysophlyctis endobiotica*), 519.
- Sciurus vulgaris*: On Apples, Pears and Hazel Nuts in Sweden, 241.
- Scleroderma domesticum*: On *Phloeosinus ihuyae*, in Hérault, 366.
- Sclerotinia*: *S. cinerea*, and *S. laxa*, 598. *S. Libertiana* ("Drop"): On Cultivated Cruciferae, in U. S. A., 594, and on Lettuce in Florida, 583.
- S. Tritohorum*: *Festuca pratensis*, *Phleum pratense* and *Poa serotina*, Resistant Vars, 519.
- Sclerospora macrospora*: On Maize; In Eritrea, 477; and in Italy, 1053.
- Sclerotium Rolfsii*: Peanuts, Resistance to Attack, 478. On Sugar Cane in Tropical, and Sub-Tropical America, Especially W. Indies, 1057. On Water Melon, in U. S. A., 238.
- Scobicia chevrii*; On Barren Privet, Fig and Vine, in Hérault, 602.
- Scolecotrichum* sp. (South American Hevea Leaf Disease): On *Hevea brasiliensis*, in Trinidad, Brit. and Dutch Guiana, 236.
- Scolytid Beetles; In Oregon, 114.
- Scudderella texensis*: On *Oxyccus macrocarpus*, in U. S. A., 495.
- Scutellista cyanea*: On *Cerooplastes galeatus*, in Uganda, 243.
- Sea Grape (*Coccoloba uvifera*), 933.
- Sea Island, Var: of Cotton, very susceptible to Black Scale (*Sissetia nigra*) in St. Vincent, 117.
- Secamone platystigma*: *Uromyces Secamores*, in Uganda, 228.
- Selenaspis*: *S. articulatus*; On Coffee and *Ficus Thomsonii*, *S. silvaticus*; On Orange in Uganda, 243.
- Selection: Of Plants Resistant to Diseases, Animal Pests, and Adverse Meteorological Conditions, in Germany, U. S. A., France, India, Australia, N. Zealand, E. Indies and Russia, 519. Vars: of Cotton, resistant to Black Scale (*Sissetia nigra*), in St. Vincent, 117.
- Senecio* spp.: *Coleosporium Senecionis* on the Andes, S. America, 926.
- Septobasidium*: *S. Acaciae*: On *Acacia Richii*, *Citrus* sp. *Gloechidium obovatum*, *Melia Azedarach*, *Prunus Persica*, *P. salicina*, *Salix glandulosa* var. *Warburgii*, and *Thea sinensis*, in Formosa, 705.

- S. pedicellatum*; On Mulberry, in Formosa and Japan, 770; *Septobasidium* sp., 770.
- Septogloeum*: *S. Arachidis*; On Peanuts, in Java; also reported from Ceylon, 350. *S. Nuttallii*; On *Osmaroma cerasiformis*, and *S. Schizonoti discolor*, in Vancouver Island, 103; *S. Salicis-Fendlerianae*; On *Salix Fendleriana* in Idaho, 103.
- Septoria*: *S. Dianthi*; On *Dianthus Caryophyllus*, in Eritrea, 477. *S. graminum*: Danish Selection of Resistant Vars; introduced into U. S. A., 138, On *Hordeum* sp. in Eritrea, 477. *S. Miconiae*: On *Miconia* sp. in Brazil, 586. *S. samarae-macrophylli*; On *Acer macrophyllum* in State of Washington, and *S. Sarcobati*: On *Sarcobatus vermiculatus*, in Montana, 103.
- Sequoia sempervirens*: *Phloeosinus sequoiae*, in Oregon, 114.
- "Seredo": Var. Cotton, resistant to Black Scale (*Saissetia nigra*) in St. Vincent, 117.
- "Sereh": Disease of Sugar Cane, 1057.
- Sesame (*Sesamum indicum*); *Cercospora* sp., in Brazil, 1058.
- Sesia pictipes*: On Peach in Ontario, 247.
- Setomorpha margalaestriata*; On Tobacco in Dutch E. Indies, 1436. Pest in stored Food Stuff in Java, 1438.
- "Sextandade barkborren" (*Pityogenes chalcographus*), 718.
- "Sgelkotten" (*Frinaceus europaeus*), 241.
- Shorea robusta*: ("Sal"): *Fomes elegans* in India, 1295.
- Shot-hole Borer (*Eccoptogaster rugulosus*), 247.
- Signiphora merceti*: Nat. Enemy of *Chrysomphalus dictyospermi* in Spain, and of *Hemiberlesia camelliae*, in Italy, 118.
- Silvanus surinamensis*; Pest in Stored Food stuff in Java, 1438.
- "Simul Tree" (*Bombax malabaricum*), 933.
- Sinapsis* spp.: *Siphocoryne* (*Aphis*) *pseudobrassicae*, in S. Africa and U. S. A., 487.
- Sindh (India): Common Farm Weeds, 484.
- Sinoxylon*: *S. sexdentatum*; Nat. Enemy of *Lonchaea aristella* on Fig, in Italy, 716. [*Sinoxylon*] *Xylobiops basilaris*, (Red-shouldered Shot hole Borer), on Pecan in U. S. A. 496.
- Siphocoryne*: *S. (Aphis) pseudobrassicae*: On *Brassica Napus*, *B. oleracea*, var *acephala*, *B. Rapa* var. *depressa*, *Raphanus sativus* and *Sinapis* spp., in S. Africa and U. S. A., 487. *S. ligustri*; On Privet, in Sweden, 241.
- Siphonella* (*Chlorops*) *pumilionis*: On Cereals in Sweden, 241.
- Siphonophora viticola* (= *Aphis illinoisensis* and *Macrosiphum illinoisensis*), (Grapevine Aphis), 367.
- Sitona lineata*: On Leguminosae, in Sweden, 241.
- "Skarptandade barkborren" (*Ips acuminatus*), 718.
- "Skatan" (*Pica pica*), 241.
- Smuts: Collection in New Mexico in 1916, 585. Injuries to Sorghum in Pres. of Bombay, 1054. Selected Danish Barley introduced into U. S. A. Resistant to *Ustilago Hordei* and *U. nuda*, 138. Selection of Maize Resistant to *Ustilago Zeae* in U. S. A., 1099. Resistance of Manitoba Wheat, 1051. See *Ustilago*.
- Smut (*Ustilago Sacchari*) of Sugar Cane, 1057.
- "Snöskatan" (*Turdus pilaris*), 241.
- "Snytbagggen" (*Hylobius abietis*), 718.
- Sodium Arsenite: Control Measures against Locusts in Capitanata, Italy, 1311.

Sodium Sulphate: For Destruction of Weeds, 713.

Soft Rot of Cruciferae; Caused by Soft Rot Bacteria (*Bacillus carotovorus*), 594.

*Solanum*: *S. Dallachii*, 364; *S. largiflorum*, (Devil's Fig), New Weed in Queensland, 364. *S. tuberosum* and *S. Wendlandii*: *Physothrips marshalli* (Females only.) on Gold Coast, 937.

*Solenopsis*. Gen. Bats, 366.

Somaliland, Italian: *Dysdercus scasellati*: On Cotton, 830. *Oxycaenus hyalinipennis*: On Cotton, 1184.

Sooty Moulds, of S. France, 821.

*Sorbus Aucuparia*: *Coleophora fuscadinella*, in Sweden, 615.

Sorghum: *Sorghum* spp. Chinch Bugs, Grass-hoppers and Kafir Ants, and Kernel Smuts; Damage in Kansas, 760. *S. halepense*: Weed in Porto Rico, 1430. *S. vulgare* (= *Andropogon Sorghum*): Smut Injuries in Pres. of Bombay, 1054.

*Sorosporaella uvella*: On Larvae of *Euxoa excellens*, in Brit. Columbia, 494.

*Sorosporium Reilianum*: On *Andropogon Sorghum*, (= *Sorghum vulgare*) in Pres: of Bombay (India) 1054.

"Sortrust" (*Puccinia graminis*), 476.

South American Hevea Leaf Disease, (*Scolecotrichum* sp.), 236.

Spain: Nat. Enemies of *Aonidiella aurantii* and of *Chrysomphalus dictyospermi* on Citrus, 118. Parasites of *Porthetria dispar*, 1432. *Phylactinia suffulta* on Oak, *Quercus palustris* and *Q. rubra* var. *americana* (Resistant Vars), 601. Spanish Mineral Products employed in Control Methods, 509.

"Spanish Oak" (*Quercus digitata*), 124.

"Spanworms" (*Geometridae*), 495.

Spelt: *Puccinia triticina*: Turkestan and Samara Vars: subject to Attack, and Resistant W. European Vars, 519.

*Spermophagus subjasciatus* (= *Sperm. musculus*): On Dwarf Beans: Disinfection Process, 605.

*Spermophilus musicus*, 1316.

*Sphacelotheca*: *S. cruenta* and *S. Sorghi*: On *Andropogon Sorghum* in Pres. of Bombay, 1054. *S. Sorghi*: On Dhari, in Eritrea, 477; and on *Sorghum* in Kansas, (U. S. A.), 760.

*Sphaerella Sacchari*: On Sugar Cane in Tropical, and Sub-Tropical America, especially W. Indies, 1057.

*Sphaerotheca*: *Sph. Humuli* (Hop Mildew): Resistant Vars in England; Individual Plants of *Epilobium montanum* and *Spiraea Ulmaria* Immune; Wild Hop of Japan, (*Humulus Lupulus* var. *cordifolius*), Attacked, in England, 232. *Sph. mors-uvae*: On Gooseberries in Norway, 476.

*Sphinx convolvuli*: (*Convolvulus Hawk Moth*), in England, 115.

"Spike Disease" of Sandalwood, (*Santalum album*) in Mysore, (India), 5.

*Spiraea*: *S. solstitialis*: Damage done by Tarring Streets of Milan (Italy) 584. *S. Ulmaria* Individual Plants immune to *Sphaerotheca Humuli*, 232.

"Spongy" (*Porthetria dispar*), 1433.

*Sporobolus elongatus*: *Helminthosporium Ravenelii*, in S. China, 330.

Spot Disease; of Cauliflower, 594; Of Apples, 1048.

Spring Canker Worm (*Paleacrita vernata*), 247.

Spruce: *Aecidium elatinum*, 1219.

*Chrysomyxa Abietis*, in England and Scotland, 363. *Physokermes abietis*, in England, 485.

"Staren" (*Sturnus vulgaris*), 241.

*Stathmopoda oestētis*: *Tachardia decorella*, in Uganda, 243.

*Stellaria* sp.; Damage done by Tarring Streets of Milan (Italy), 584.

Stem. Diseases of: Cranberry; Endrot (*Fusicoccum pulrefaciens*), 237.

Cruciferae, S. Rot (*Bacterium campestre*). Sugar Cane; S. Rot (*Gnomonia Iliou*), 1057. Watermelon;

S. Blight (*Mycosphaerella citrullina*) and S. Endrot (*Diplodia* sp.), 238.

*Stenobothrus*; Sp.: of Locusts in Capitanata (Italy), 1311.

*Stephanitis*: S. *pvi*: On Pear, 944.

S. *rhododendri*: On Rhododendrons, in France, 944.

*Stictococcus*: On Gold Coast — S. *multispinosus* on *Cola acuminata*; and

S. *sjöstedti* on Cacao, 242. In Uganda — S. *coccineus*: On *Acacia* sp. with *Ceroplastes subdennatus*, 243; S. *diversiseta*; On *Anona*

*muricata*, *Artocarpus integrifolia*, Cacao, *Cajanus indicus*, *Croton Tigrum*, *Dolichandrone platycalyx*, *Hibiscus* and *Morus*, and preyed on by *Eublemma costimacula*, 243. S.

*formicarius*, On *Ficus* sp., 242, 243; S. *gowdeyi* on Coffee and *Haronga madagascariensis* 243; S. *multi-*

*spinosus*; On *Dolichandrone platycalyx* (= *Markhamia platycalyx*) 242.

*Stictolobus*: S. *subulatus* (= *Membracis sublata*), 1067. S. *trilineatus* n. sp.; On Cypress in Louisiana (U. S. A.), 1067.

"Stikkelsbaerdræperen" (*Sphaerotheca mors-uvae*), 476.

Stinking Roger (*Tagetes minuta*), 932.

*Stipa eminens* var. *Andersonii*: *Tilletia Wilcoxiana* in Santa Catalina (California), 228.

"Stjälkbocken" (*Phylocia cylindrica*), 121.

*Stomacoccus platani*: On *Platanus racemosa*, in California, 123.

"Stora krusbärsstekeln" (*Pterodinea* (*Pteronius*) *ribesii*, 241.

Strawberry: *Agriotes lineatus* and *Anthonomus rubi* in Sweden, 241.

Var. Minnesota, No. 1017, slightly resistant to Cryptogamic Diseases, U. S. A., 298.

Strawberry Tree: *Charaxes jasus* in Hérault, 366.

"Stribesyge" (*Pleospora graminea*), 1302.

*Stromatum fulvum*: On Cork Oak, in Algeria and on Young Elm in Hérault, 602.

*Strophanthus gratus*: *Physothrips marshalli* on Gold Coast, 937.

*Struthanthus flexicaulis*: *Dialcurodes* (*Gigaleurodes*) *struthanthi*, in Brazil, 933.

*Sturnus vulgaris*, in Sweden, 241.

*Stypinella Tanakae* (= *Helicobasidium Tanakae* and *Septobasidium* sp.) in Japan, 705.

Sugar Beet: *Autographa californica* in U. S. A., 1062. *Gloeosporium Betae* in Montana, 103. *Heterodera schachtii*: Series of Trials to obtain Type resistant to this Pa-

rasite, in Germany, 519. *Nysius ericae* (= *N. angustatus*) in U. S. A., 1185.

Sugar Cane: Diseases in Tropical and Sub-Tropical America, especially the West-Indies, 1057. Disease Resistant Varieties at Porto Rico, 1239. Frost Damage, Method Recommended in the Argentine for Protection, 1201. *Ipobraccon grenadensis*, I. *saccharatus* and *Micro-*

*dus diatraeae*; On *Diatraea saccharalis*, in Brit. Guiana, 935. *Lepidiotia albohirta* and *L. frenchi* in Queensland, 246. *Odontia Sacchari* and *O. saccharicola* in Porto Rico, 1176. "Otahitū" or "Caña blanca" Var.; Subject to Disease, Porto Rico, 1239. *Pseudococcus sacchari* in Brit. Guiana and *Ps. virgatus* in Zanzibar, 242. *Scap-teriscus vicinus*, In Porto Rico, 1063.

- Tomaspis saccharina*, Sugar Cane Froghopper in Grenada and Trinidad and its Nat. Enemies, 939.
- Sumatra : *Cylas tucipennis*, On Sweet Potato, 936.
- Surinam, see Dutch Guiana.
- Suttons Improved Petit Pois' Var : of Peas Resistant to *Pseudomonas seminum*, in England, 595.
- "Svarta mårborren" (*Myelophilus piniperda*), 241.
- Swedes : Selection of Vars. Resistant to *Plasmodiophora Brassicae*, in Denmark, 282.
- Sweden : Animal Pests of Cultivated Plants, Observations made from 1912-1916, 241. Birch Oak, Apples Pears, and *Sorbus Aucuparia*, etc.; *Coleophora fuscedinella*, 615. Carrots; *Phytoecia cylindrica*, near Stockholm, 121. Cereals; Resistance to Rust, Lodging and Cold, 143. Cucumber; *Ascochyta Cucumis*, *Fusarium nivium* (?) *F. redolens*, var. *angustius* and *F. sclerotoides*, *Verticillium albo-atrum* (Wilt), in Ballersta etc., 596. Forest Trees; Injurious Insects in 1916, 718. Spring Wheat; Vars: Resistant to *Fusarium culmorum*, 1297; and Influence of Date of Earling on Damage done by *Contarinia tritici*, 1312. Wheat, Oats and Barley; *Cicadula sevnotata*, 1313.
- Sweet Potato : *Cylas formicarius*, in Porto Rico and Means of Control, 1434; *C. f.* in the Philippines, 864; *C. f.* var. *elegantulus*, 936. *Hypothenemus ritchiei*, On Dried Sweet Potatoes, in Jamaica 608. Mosaic Disease and Root Rot in the Philippines, 864. *Scaptieriscus vicinus*, in Porto Rico, 1063. Weevils; On Tubers, 936.
- Sweet Potato Weevil (*Cylas formicarius*, var. *elegantulus*), 936.
- Switzerland : *Diaporthe taleola*; On Oaks, 362.
- Sycamore (*Platanus racemosa*); *Stomacoccus platani*, in California, 123.
- Sycamore Fig Tree Psylla, 487.
- Sycophila incerta* : Reared from *Ficus laurina*, in W. Indies, 934.
- Sycosoter lavagner* : On *Hypoborus ficus*, in France, 120.
- "Sylvaner blanc", Vine offering Relative Resistance to Mildew, 105.
- Symydobius chrysolepis* : *Closterocerus utahensis* (*C. californicus*) reared from *S. c.*; On *Quercus chrysolepis*, in California, 934.
- Synchytrium endobioticum* : On Potatoes, in Norway, 476.
- Synotus*, 1061.
- Syntomaspis* : On *Rhynchites bacchus* in Sicily, 374.
- Syringa vulgaris* : Damage done by Tarring Streets of Milan (Italy), 584.
- Systema frontalis* : (Cranberry Flea-beetle) On *Oxycoccus macrocarpus* in U. S. A., 495.
- TABAKSBOEBOEK (*Lasioderma serri-corne*), 1436.
- "Tabaksmot" (*Setomorpha marginalae-struata*), 1436.
- Tachardia* : *T. decorella*; On *Anona muricata*, in S. Africa, and Uganda, 242. 243. On *Psidium Guajava* in Uganda, 243. *T. longisetosa*; On *Anona muricata*, *Ficus Thonningii* and Guava, in Uganda, 243.
- Tagetes minuta* (Mexican Marigold); Weed in Rhodesia, 932.
- Tahiti : *Aspidiotiphagus citrinus*. Nat. Enemy of *Aspidiotus destructor*, living on Coconuts, 118. *Ptychodes trilineatus* : Three Lined Fig, Tree Borer, 248.
- Tallfayet (*Panolis griseovariegata*), 718.
- "Tallkultur säckspinnarestekeln" (*Lyda hieroglyphica*), 718.
- "Tallmätaren" (*Bupalus piniarius*), 718.

- Talpa europaea*, in Sweden, 241.  
*Tamarix* sp. *Aphis tamaricis*, in Egypt, 487.  
 "Tallsteklarna" (*Lophyrus pini*, L. *sertifer*), 718.  
 Tamarind: *Aspidiotus orientalis*, in Coimbatore, 242.  
 "Tandu" or "Tannan" (*Pseudomonas Tritici*), 592.  
 "Tantovina" White Grape, Var: Offering Relative Resistance to Mildew in France, 105.  
*Taonabo japonica*: *Aleurolobus taonabae*, in Japan, 933.  
 Tarring: Observations on Damage caused by Tarring Streets of Milan (Italy), 584.  
*Tarsonemus frugariae*, in Norway, 476.  
*Taxus baccata*: Damage done by Tarring Streets of Milan (Italy), 584.  
 Tea: *Aspidiotus transparentis*, *Cero-plastes ceriferus*, *Coccus discrepans* in Uganda, 243. *Hypochnus* sp.; in Ceylon, 109. *Phyothrips lefroyi* and *Phys. setiventris*, in India, 941. *Pulvinaria psidii*, in Uganda, 243.  
*Tecoma stans*: *Eulecanium somereni*, in Uganda, 243.  
 "Teff" (*Eragrostis abyssinica* = *Poa abyssinica*), 1427.  
 Temperature: Direct Effect of Low Temperature on Winter Cereals, in U. S. A., 257.  
*Tenebrioides mauritanicus*: Pest in Stored Food Stuffs in Java, 1438.  
*Tetramorium*, 366.  
*Tetranewa ulmi*: On Elms in S. E. Russia, 1180.  
*Tetranychus pilosus* (*T. mytilaspidis*?), (Red Spider): On Apple and Plum in Ontario, 247.  
*Tetrao urogallus*, in Sweden, 241.  
*Tetrastichus*: *T. caridei*: Nat. Enemy of *Pulvinaria flavescens*, *P. minuta* and *P. platensis* in Argentina, 1308. *T. epilachnae*; On *Chilocorus bipustulatus*; Nat. Enemy of *Chrysomphalus dictyospermi*, 118. *T. gowdeyi*, in *Pulvinaria jacksoni*, in Uganda, 243. *T. isis*, Possibly Parasitic on *Oiceticus* in S. Brazil 714.  
 Texas: *Acciduum Gossypii*: (Cotton Rust), 479. *Aleyrodidae*, 933. *Cylas formicarius* var *elegantulus*, on Sweet Potato, 936. *Macrosiphum illinoensis*, (Grapevine Aphid), 367. *Ptychodes trilineatus*, Three Lined Fig Tree Borer, 248.  
*Thagora figurana*: Pest in Stored Food Stuffs in Java, 1438.  
*Thaneroclerus buquet*; Pest in Stored Food Stuffs in Java, 1438.  
*Thea sinensis*: *Helicobasidium Tanakae* (= *Styphmella Tanakae*), in Japan, 705. *Septobasidium Acaciae*, in Formosa, 705.  
*Theobroma Cacao*, see Cacao.  
*Thersilochus coeliadicola*. On *Coeliodes ruber*, injurious to Hazel Nut in Italy, 614.  
*Thielavia basicola*: On Tobacco, Vars. Broad Leaf Burley, and Irish Gold, in Ireland, 1916, 49.  
*Thielaviopsis paradoxa* (Pine Apple Disease): On Sugar Cane in Tropical and Sub-Tropical America, especially W. Indies, 1057.  
*Thlaspi arvense* (Fan weed); amongst Cereals in Montana, 639.  
 Thread Blight, Of Cacao, Mycelium resembling *Corticium*, 493.  
 Thread Blight (*Hypochnus Sacchari*): Of Sugar Cane, 1057.  
 Three Lined Fig-Tree Borer (*Ptychodes trilineatus*), 248.  
 Thrips: *T. denticornis*, On Cereals in Norway, 476. *T. tabaci*, On Onions in Indiana, 422.  
*Thunbergia erecta* and *T. laurifolia*: *Phyothrips marshalli*, on Gold Coast, 957.  
 Thuya: *T. plicata*: *Phloeosinus punctatus* and *Phl. sequoiae*, in Oregon, 114. *Thuya* sp.; Damage Done by

- Tarring Streets of Milan (Italy), 584.
- Thyridaria tarda*: On Sugar Cane, in Tropical, Sub-Tropical America, Especially in W. Indies, 1057.
- Tilna*: Damage Done by Tarring Streets of Milan (Italy), 584.
- Tilletia*: *T. levis* and *T. Triticci*; Resistant Vars of Wheat in India (Pusa), Australia, N. Zealand, 519.
- Tilletia* spp.: On Cereals in Norway, 476. *T. Wilcoxiana*; On *Stipa eminens* var. *Andersonii*, in Santa Catalina (California), 228.
- Tipula oleracea*: On Barley and Oats in Norway, 476.
- Tjädern (*Tetrao migallus*), 241.
- "Tjeribon" (slightly resistant) Cross with "Tschun" Var. Sugar Cane showing Resistance to Disease, in E. Indies, 519.
- Tmetocera ocellana* (Bud Moth): On Apple, Cherry, Peach, Pear and Plum, in Ontario, 247. On Fruit Trees, in Sweden, 241.
- Tobacco: Resistant Type in Germany, to *Bacillus maculicola*, 519. *Cercospora solanicola*, in Brazil, 1058. Insects and Fungoid Pests on Var. "Tabac bleu". Réunion Tobacco Grown in Mauritius; *Achatina ponderosa*, *Erysiphe*, *Fusarium*, *Heliothis armigera*, *Heterodera*, *Pythium de Baryanum*, and Aunts, 942. *Lasioderma serricornis* and *Setomorpha margalaestriata*, in Dutch E. Indies, 1436. *Scapteriscus vicinus*, in Porto Rico, 1063. *Thielavia basicola* (Root Rot); Vars: Broad Leaf Burley and "Irish Gold" very susceptible in Ireland, in 1916, 49.
- Tobago: Order of the Govt. of the Colony of Trinidad and Tobago placing the Coconut Butterfly (*Brassolis sophorae*) among Plant Pests, 1171.
- Tolyposporium filiferum* ("Long Smut"): On *Andropogon Sorghum* in Pres. of Bombay, 1054.
- "Tolytandade barkborren" (*Ips sexdentatus*), 718.
- Tomaspis*: *T. pictipennis*, 939. *T. saccharina*: On Sugar Cane in Grenada, 939. *T. varia*, 939.
- Tomato: *Phoma destructiva*, in Tunis, 1306. *Scapteriscus vicinus*, in Porto Rico, 1063.
- Tomicus (Hylastes) nigrinus*: On *Pseudotsuga taxifolia*, in Oregon, 114.
- "Tonchio del fagiuolo" (*Acanthoscelides obtectus*), 605, 606.
- "Tondini" (Small Var. Bean); *Acanthoscelides obtectus*, 606.
- "Top Rot": Of Sugar Cane, 1057.
- Tortrix argyrospila* (Fruit Tree Leaf Roller); On Apple, Cherry, Peach, Pear and Plum in Ontario, 247. *T. resinella*; On Forest Trees in Sweden, 718.
- Tortrix* Moth: Injurious Attacks; On Pine Woods, in France, 1061.
- Tortricid Moth: (*Carpocapsa splendana*); In Chestnuts (?), 1066. *Evetria bouliana*, (Pine Shoot T. M.), 948, 1061. *Ev. (Retinia) resinella*, 1061. *Ev. turionana*, (Pine Bud T. M.), 1061.
- "Touching" of Figs in Prov. of Naples, 716.
- Toxicity, Relation of Volatility of Organic Compounds used as Insecticides to their Toxicity, 7.
- Toxoptera aurantii*: Destroyed by *Chilocorus bipustulatus*, in France, 828.
- Trabutna chinense*: On *Ficus* sp., in S. China, 350.
- Trachycarpus*: Damage done by Tarring Streets of Milan (Italy), 584.
- "Traminer Rose", White Grape var. offering Relative Resistance to Mildew, 105.
- Transvaal: Coccids in 1917, 244.
- Uromyces pedicellatus*, Rust on *Era-*

- grostis abessinica* (= *Poa abyssinica*) and *E. curvula*. 1427.
- Trautmann, Bacillus of. 1316.
- Tribolium castaneum*, Pest in Stored Food Stuffs in Java. 1438.
- Tribulus terrestris*; Farm Weed in Sindh (India), 484.
- Trichomonas*: On Field Mice in Italy, 1318.
- Trichosphaeria Sacchari*: On Sugar Cane in Tropical, Sub-Tropical America, Especially the W. Indies, 1057.
- Trinidad: *Aleyrodidae*, 933. Order of Govt. of Colony of Trinidad and Tobago placing the Coconut Butterfly (*Brassolis sophorae*) among Plant Pests, 1171. *Pachymerus quadrimaculatus*, Weevil on Black Eye Pea (*Vigna Catjang*) and Cow Pea (*V. unguiculata*), 1182. S. American Hevea Leaf Disease: On *Hevea brasiliensis*, 236. *Tomaspis saccharina*, On Sugar Cane and its Nat: Enemies, 939.
- Triosa: *T. alacris* (= *T. laura*); On Laurel in New Jersey, 1064. *T. viridula*; On Carrots in Sweden, 241.
- Triphleps insidiosus*: On *Blissus leucophterus*, in Illinois, 1431.
- Tripoli; Oasis of: Aphides, *Cuscuta*, and *Uromyces striatus*: On Alfalfa, 163. *Opius concolor*, Endophagous Braconid Parasite of Olive Fly (*Dacus oleae*), 1181. Root Rot of Citrus, 1292.
- Triticum Spelta*: Vars: from Turkestan and Samara very subject to *Puccinia triticea*, compared with Resistant West European Types, 519.
- Trogocarpus ballestrerii* (= *Megastigmus ballestrerii*): On Pistaccio and Turpentine, in Sicily, 831.
- "Troiano" (Fig Var) *Lonchaea aristella*, in Italy, 716.
- Trophis racemosa*: *Aspidiotis* (*Pseudacnidia*) *tesseratus*, in Jamaica, 242.
- Tropism (Physical Factors of), 1209.
- Trypodendron*: In Oregon: — *T. (Xyl.) loterus* and *T. (Xyl.) politus* (?), 114. *T. rufitarsis*; On *Pinus contorta*, and *Trypodendron* sp.; On *Pseudotsuga taxifolia*, 114.
- Trypopermion*: *T. latilhorax* (In Bolivia and Peru), and *T. sanfordi*, n. sp. (In Peru); On Irish Potato Tubers, 114.
- "Tschun"; Resistant Hindu Var: of Sugar Cane, in E. Indies, 519.
- Tsuga*: *T. canadensis* (Hemlock Tree) *Fomitiporia tsugina* in New Hampshire and N. York States, 110. *T. heterophylla*: *Gnathotrichus sulcatus*, *Gn. retusus*, and *Platypus wilsoni*, in Oregon, 114.
- Tumours; Of Cluster Pine (*Pinus Pinaster*), in France, 600.
- Tunis: *Phoma destructiva* On Tomato, 1306.
- Turdus merula* and *T. pilaris*, in Sweden, 241.
- Turnip: *Agriotes lineatus*, *Chorthippa* (*Phorbia*) *brassicae*, *Eurydema oleracea*, *Lygus pratensis*, *Phyllotreta* sp, and *Plutella maculipennis*, in Sweden, 241. *Autographa californica* (Alfalfa Looper) in Brit. Columbia, 1062.
- Turpentine: *Megastigmus ballestrerii* (= *Trogocarpus ballestrerii*), in Sicily, 831.
- Tylenchus*: *T. devastatrix*: On Clover in Sweden, 241. *T. penetrans*; On Cotton, Potato etc. in U. S. A., 491.
- Tylococcus insolitus*, in S. Africa, 244.
- Tyndarichus navae* and *Tyndarichus* sp.: Parasitic on Eggs of Gypsy Moth, (*Porthetria dispar*), 1432.
- Typhlopsylla*; On Field Mice in Italy, 1318.
- UGANDA: Coccidae, 242, 243. Fungi 228. *Lycidocoris mimeticus* var. A. at Lubowa, 940. *Physothrips humuminae*, On *Funtumia elastica*, 937.

*Puccinia Coreopsidis*, On *Coreopsis* 1295.  
*Ulmus*: *U. campestris*, var *cornubiensis*, and *U. Dampieri* var *aurea*: *Gossyparia ulmi*, in England, 485. *U. effusa*: Damage done by Tarring Streets of Milan (Italy), 584.  
*Uncinula necator*: See *Oidium*.  
 United States: *Acanthoscelides obtectus*, 606. *Aecidium Gossypii*; On Cotton in Texas and Florida, 479. *Agriolimax agrestis*; On Vegetables in N. Y. State, 943. *Aleyrodidae*, 933. *Apanteles lacteicolor*: On *Euproctis chrysorrhoea* imported into U. S. A. from Europe, 1433. Apple Spot Diseases, 1048. Arachids resistant to *Sclerotium Rolfsii* in Virginia, 478. Asparagus Resistant to *Puccinia Asparagi* in Massachusetts, 285. *Autographa californica*; On Various Cultivated Plants, 1062. *Bacillus Solanacearum*; On Castor Oil, 1055. *Bacterium translucens*; On *Hordeum* spp. 593. *Blissus leucopterus*, and its Nat. Enemies, in Illinois, 1431. *Carya olivaeformis* and its Nat. Enemies, 496. *Cercospora personata*: On Peanut, 350. Chalcids, N. American, 934. *Clytus devastator*; On Citrus etc., in Florida, 1437. *Colleto-trichum Lini*; On Flax, 1305. *Corythucha spinulosa*; On *Prunus serotina* in N. Jersey, 717. Cranberry (*Oxycoccus macrocarpus*), Insects Injurious to, in Massachusetts, New Jersey, Wisconsin, Long Island and on NW. Coast of Pacific, near Columbia, 495. *Cronartium occidentale*; On *Pinus edulis*, *P. monophylla*, *Ribes* spp. and *Grossularia* spp. in Arizona and Colorado, 1428. Cruciferae, Cultivated; Diseases of, 594. *Cylas formicarius* var *elegantulus*; On Sweet Potato, 936. Cynipidae; On *Castanopsis* spp. and *Quercus* spp., 124.

Education, Phytopathological, 127. Endrot of Cranberries, 237. Eradicating Tall Larkspur on Cattle Ranges in U. S. National Forests, 55. *Euxoa excellens* in California, Colorado and Oregon, 494. Flax-wilt, (*Fusarium Lini*); Nature and Inheritance of Wilt Resistance, 283. *Fomitiporia tsugina*; On *Tsuga canadensis* in States of N. Hampshire and N. Y., 110. Frost, Orchard heating against, in Utah, 726. Fruit Trees resistant to Cold in U. S. A., 519. Fungi N. America, 103. *Hoplia floridana*, n. sp.; On Citrus, in Florida, 946. Hop Mildew, 232. Hybrid Chestnuts immune from *Diaporthe parasitica* (= *Endothia parasitica*), 286. Introduction into U. S. A., 1914: *Festuca elatior*, resistant to Rust (*Puccinia*), *Castanea mollissima*, resistant to Bark Disease, New Era Potato, immune to Blight (*Phytophthora infestans*), from N. Zealand, and Selected Danish Barley resistant to *Ustilago Hordei*, *U. nuda* and *Septoria graminum*, 138. *Keithia Chamaecyparissi*; On *Chamaecyparis thyoides*, in N. Jersey, 1307. *Macrosiphum illinoisensis*, Grape Vine Aphid, 367. Maize: Selection of Vars. resistant to Smut, (*Ustilago Zeae*), 1099. *Nezara viridula* and Kernel Spot of Pecan, 927. *Nysius ericae*; On Sugar Beet and cultivated Cruciferae, 1185. Pecan Insect Pests and Control, in South U. S. A., 496. *Phthorimaea operculella*; On Potatoes in California and Indiana, 1183. *Phychodes trilineatus*, Three-Lined Fig-Tree Borer, 248. *Pulvinaria cupaniae*; On Mulberry imported from U. S., Jamaica, 242. *Rhagoletis pomonella*, In California, Colorado, Washington State, 122. Rusts and Smuts collected in N.

- Mexico, 1916, 385. Scolytid Beetles; In Oregon, 114. Selection of Plants Resistant to Diseases, Animal Pests and Adverse Meteorological Conditions, 519. Sorghum Disease and Remedy, in Kansas, 760. *Stictolobus trilineatus*; On Cypress, in Louisiana, 1067. *Stomacoccus platanti*; On *Platanus racemosa* in California, 123. Strawberry, Minnesota No. 1017 only slightly resistant to Cryptogamic Diseases, 298. Sugar Cane, Diseases of, 1057. Sweet Corn resistant to *Chloridea obsoleta*, 279. *Tilletia Wilcoxiana*; On *Stipa eminens* var *Andersonii* in Santa Catalina Is. (California), 228. *Trioza alacris*; On Laurel in N. Jersey, 1064. *Tylenchus penetrans*; On Cotton, Potatoes *Viola* spp., etc in N. Carolina and Georgia, in Michigan and in N. Y. State respectively, 491. Vine: Resistance to Cold in Kentucky, 384. Watermelon, Diseases of, 238.
- "Unshu [Satsuma] Orange" (*Citrus nobilis* var *unshiu*), 102.
- "Upland" Cotton: Attacked by *Tylenchus penetrans* in N. Carolina, 491.
- Uredinales: Of the Andes, S. America, 926. Rusts and Smuts collected in New Mexico, in 1916, 585.
- Uredo: *U. cantonensis*; On *Melothria indica*, in S. China, 350. *U. Erythroxylonis*; On *Erythroxylon Coca*, on the Andes (S. America), 926. *U. philippinensis*; On *Cyperus* sp. in S. China, 350.
- Uromyces: *U. Eragrostidis*; On *Eragrostis cynosuroides* and *E. pectinacea*, in Transvaal, 1427. *U. linearis*; On *Panicum repens*, in S. China, 350. *U. pedicellatus*; On *Eragrostis abyssinica* (= *Poa abyssinica*) and *E. curvula*, in Transvaal, 1427. *U. Secamones*; On *Secamone platystigma*, in Uganda, 228. *U. striatus*; On Alfalfa in the Oasis of Tripoli, 163.
- Ustilago*: *U. Avenae*; Resistant Vars: of Oats in U. S. A., 519. *U. Avenae* var. *levis*; On *Avena abyssinica* in Eritrea, 477. *U. Cynodontis*: On *Cynodon Dactylon*, in S. China, 350. *U. Hordei*: Selected Resistant Danish Vars. of Barley; introduced into U. S. A., 138; On *Hordeum* sp. in Eritrea, 477; On *Hordeum trifurcatum* in New Mexico, 585. *U. Koordersiana*; On *Polygonum* sp. in S. China, 350. *U. levis*: on Oats in New Mexico, 585. *U. nuda*: Selected Resistant Danish Vars. of Barley introduced into U. S. A., 138. *U. Sacchari*; On Sugar Cane in Tropical, Sub-Tropical America, especially W. Indies, 1057. *Ustilago* spp. on Cereals in Norway, 476. *U. Tritici*: On Wheat in Java, 1426; Resistant Spring Wheat var "Schlanstedter" in Germany, 519. *U. Zeae*: Selection of Resistant Vars: of Maize, in U. S. A., 1099.
- Ustilagopsis deliquescens*: On *Paspalum distichum*, in Argentina, 179.
- Ustilina*: *U. Mori*: On *Morus alba*, in Japan, 705. *U. vulgaris*: On Lime Trees, in France, 711.
- Utah (U. S. A.): *Autographa californica*, 1062. Orchard Heating Against Frost, 726.
- "Uva damascena" (Black Morocco Var. Vine), 715.
- "VALENCIA", Var: of Peanuts very susceptible to *Sclerotium Rolfsii*, in Virginia, 478.
- Valsa Paulowniae*: in Japan, 705. *Valvucystia rhopaloides*: Nat: Enemy of *Oryctolagus hyalimipennis* in Italian Somaliland, 1184.
- Vanilla aromatica*: Host of *Diaspis*

- boisduvali*, attacked by *Aspidiotiphagus lounsburyi*, in Italy, 118.
- "Vanliga ärttripsen" (*Physopus robusta*), 241.
- "Vanliga knopprecklaren" (*Argyroplaca [Olethreutes] variegana*), 241.
- "Vättersorken" (*Arvicola terrestris*), 241.
- Vellosiella*: N. Gen. Hyphomycetes, 586.
- Venezuela: *Ptychodes trilineatus*, on Fig, 248.
- "Verde-secco": Of Fruit Trees in Apulia (Italy), 1318.
- Verticillium albo-atrum*; On Cucumber in Sweden, 596.
- Vespertiho*, 1061.
- Vespertilionidae (*Vesperugo*), 1061.
- Vesperugo noctula*, *V. pipistrellus*, *V. serotinus*, 1061.
- Vetch: *Acanthoscelides obtectus*, 606.
- "Vetemyggan" (*Contarinia tritici*), 241, 1312.
- Vicia Faba* and *V. sativa*: *Acanthoscelides obtectus*, 606.
- Victoria (Australia): Downy Mildew of the Vine, 359. *Physothrips kellyanus*: On *Hypochoeris radicata*, 937.
- Vigna Catjang*, (Black Eye Pea) Red Grain: *Ceroplastodes cajan*, in Coimbatore, 242. *Fusarium tracheiphilum* and *Heterodera radiclea*; Iron Var. and Iron, Black, and Whippoorwill Vars: Cross, Resistant to Attack, in U. S. A., 519. *Nezara viridula* in Georgia, U. S. A., 927. *Pachymerus quadrimaculatus* in Trinidad, 1182.
- Vigna unguiculata*: (Cow Pea) *Pachymerus quadrimaculatus*, in Trinidad, 1182.
- Vine: *Aleurolobus taenabae*, in Japan, 933. *Aspidiotus cydoniae*; in Coimbatore, 242. *A. (Pseudaonidia) fossor*, in Brit. Guiana, 242. Comparison of Effects of Copper and Acid Mixtures on Mildew, 590.
- "Chlorosis"; Resistance of Stock imported from France into Sicily 651. *Dictyothrips aegyptiacus*; On "Black Morocco" Var, in Cyrenaica, 715. Downy Mildew (*Plasmopara viticola*) in Australia, 359. See also *Plasmopora viticola*. Downy and Powdery Mildews, Black Rot and Winter Injury in U. S. A., 425. Effect of Pruning on Grafted Vines, 1251. Locusts, in Capitanata, (Italy), 1311. *Macrosiphum illinoisensis*, in U. S. A., 367. *Otiorrhynchus sulcatus*; Parthenogenetic Reproduction in France, 116. *Phora fasciata*; Parasite of *Coccinella septempunctata*, in France, 119. "Phylloxera"; Trials in Germany to obtain Resistant Vars, 519; Attacks in U. S. A., 425. *Pimpla alternans*, Reared in Winter Chrysalis of *Clysis ambiguella*, in Hérault, 366. Polysulphide; Action of, against Oidium, 931. *Scobicia chevrei*; in Hérault, 602. Service of "Preventive Detection" of Mildew, Phytopathological Observatory of Turin, 925. Simple solutions of Copper Sulphate against Mildew, 822. *Uncinula necator* (Oidium), 232. Vars: Resistant to Attacks of Black Rot, Black Rust, *Botrytis cinerea*, Bramble Leaf Disease, Brown Rot, Chlorosis, Mildew, Oidium and Phylloxera; See Resistance of Plants.
- Viola* spp: *Tylenchus penetrans*, in N. York, State, 491.
- Vipers' Grass: *Agriotes lineatus* in Sweden, 241.
- Virginia: *Macrosiphum illinoisensis*, 367. *Sclerotium Rolfsii*; Comparison between Resistant Qualities of Peanut Vars, 478.
- "Virginia Bunch and Virginia Runner: Vars. of Peanut resistant to *Sclerotium Rolfsii* in Virginia, 478.
- Virginia Creeper, (*Vitis hederacea*):

*Uncinula necator* in U. S. A., 232.

Virus: Preparation of Active Virus against Field Mice, and Method of Applying it in Fields infested by these Rodents, 1316.

"Vissnesjuka" (*Verticillium albo-atrum*), 596.

*Vitis*: *V. europaea* × *V. Labrusca* Hybrids. Resistant to Black Rot, Mildew and Oidium, in France, 519. *V. hederacea* (Virginia Creeper); attacked by Vine Mildew (*Uncinula necator*), 232. *Vitis* sp: *Helicobasidium Tanakae* in Japan, 705; and *Macrosiphum illinoensis* in U. S. A., 367.

WALNUT CATERPILLAR (*Datana integerrima*), 496.

*Warpuna clandestina*: *Helminthosporium Warpurae*, in England, 1424.

Washington (State of): *Autographa californica*, (Alfalfa Looper), 1062. *Rhagoletis pomonella*, (Apple Maggot or Railroad Worm), 122.

Water Melon: (*Citrullus vulgaris*); 1062. In U. S. A. *Autographa californica*, 1062. *Bacillus tracheiphilus*, *Colletotrichum lagenarium*, *Diplodia* sp., *Fusarium nivium*, *Heterodera radiculicola*, *Mycosphaerella citrullina*, *Peronosplasmopara cubensis*, *Sclerotium Rolfsii*, Blossom end Rot, and Malnutrition, 238. Conqueror Var., resistant to *Fusarium nivium* in U. S. A., 519.

Weeds, Harmful: Control of Weeds in Rice Fields by Rolling, 1106. Control of Wild Rice in Italy, 161. *Delphinium exaltatum*; Poisoning of Cattle Ranges in U. S. National Forests; Methods of Irradiation, 55. Destroying Weeds by Carp Breeding in Transplanted Rice Fields, at Vercelli (Italy), 78. Destruction by Sodium Bisulphate, 413. Devil's Fig (*Solanum large-*

*florum*) in Queensland, 364. Farm Weeds in Sindh (India), 481. *Imperata arundinacea*, extirpated by *Leucaena glauca* in the Philippines, 1123. *Imperata exaltata* (Cogon Grass), Breeding Place for Locusts, in the Philippines, 53. *Kennedya rubicunda*, to Forest Trees in New South Wales, 239. "Once Over" Quack Grass Killer, 1273. Relation of Weed Growth to Nitric Nitrogen Accumulation in the Soil, 730. Shubert Weed and Sprout Destroyer, 334. *Sorghum halepense* in Porto Rico, 1430. Worst Weed, amongst Cereals in Montana, 639. "Weisser Kloeuvner" Or Pinot blanc vrai", White Grape Var. offering Relative Resistance to Mildew, 105.

"Western Chinquapin" (*Castanopsis sempervirens* and *C. chrysophylla*), 124.

West Indian Mole Cricket (*Scapteriscus vicinus*), 1063.

Wheat: *Agriotes lineatus* in Sweden, 241. Black Rust in Wheat, (Australian Interstate Conference of Agricultural Scientists), 1076. Bon Fermier and Japhet, Resistant to Smut, 1051. "Bore" and "Line" 0728 and Resistance to Rust, 519. *Cecidomyia aurantiaci* in Norway, 476. *Cicadula septentata*; in Sweden, and Resistant, Varieties, 1313. Cold: Resistant Varieties in France, 157. *Contarinia tritici* in Sweden, 241. *Gibberella Saubinetii* (= *Fusarium rostratum*), *Helminthosporium geniculatum*, *H. gramineum*, *Nigrospora Panicis* and *Ustilago Tritici*, in Java, 1426. Locust in Capitanata, 1311. Manitoba Wheat Resistant to Rust, 34. *Pseudomonas Tritici*; in Punjab, 593. Resistance of Manitoba Wheat to Fungous Diseases, 1051. "Schlanstedter" Spring Wh. re-

- sistant to *Ustilago Tritici* in Germany, 519. Selection of Var, Resistant to Rust and Lodging in India, 854. Spring Wheat: Influence of Date of Earling on Damage done to by the Dipteron *Contarinia tritici*, in Sweden and Varieties Suffering Least, 1312. Spring Var Resistant to *Fusarium culmorum* in Sweden, 1312. Vars Resistant to Rust, to *Tilletia laevis* and *T. Tritici* in India, Australia and N. Zealand, 519. Weevily Wheat for Feeding Poultry, 1019.
- "Whippoorwill": Var. of Vigna Catjang resistant to *Fusarium tracheiphilum* and *Heterodera radiculicola*, in U. S. A., 519.
- White Ants (Termites): *Leucotermes flavipes*, etc., On Pecan in U. S. A., 496.
- White Grubs: *Dyscinetus trachyphylus*, *Lachnosterna grandis*, *Phytalus georgianus*, On Cranberry in U. S. A., 495.
- White Marked Tussock Moth (*Hemerocampa leucostigma*), On Fruit Trees in Ontario, 247.
- White Rust of Cruciferae (*Albugo candida* = *Cystopus candidus*), 495.
- Willow, White: *Evocentrus punctipennis*, in Languedoc, 602.
- Wild Cherry (*Prunus serotina*): *Corythuca spinulosa*, in N. Jersey, 717.
- Wild Elm: *Ceroplastes ceriferus* in Coimbatore, 242.
- Wild Pepper grass (*Lepidium apetalum*), 368.
- Wilt: Of Cultivated Cruciferae; (Foot rot, Wilt) (*Fusarium conglutinans*); and Root Rot (Wilt), Disease of Non-Bacterial Origin Caused by Asphyxia of the Plant due to Stagnation of Water, 594. Of Sugar Cane (*Cephalosporium Sacchari*), 1057.
- Wisconsin: *Aleyrodidae*, 933. Bacterial Blight (*Bacterium translucens*) of Barley, 593. Insects Injurious to Cranberry, (*Oxycoccus macrocarpus*), 495.
- "Wither Tip" of Sugar Cane, 1057.
- Woolly Aphis (*Eriosoma lanigera*), 247, 628.
- Worms: Nat: Enemies of Field Mice in Italy, 1318; Cause of Deformities on Fruit Trees, in Sicily, 610.
- Wyoming (U. S. A.): *Autographa californica*, 1062.
- "X. L. ALL": Insecticide used in Holland against *Stephanitis rhododendri*, 944.
- Xiphidium fasciatum*: Grasshopper feeding on Froghoppers in Grenada, 939.
- Xisticus lanio*: On *Coeliodes ruber*; Injurious Coleopteron on Hazel Tree, in Italy, 614.
- Xylaria* (*Xyloglossa*) *obovata*, *Xyl.* (*Xylogl.*) *scopiformis* var *heveana*, and *Xyl.* (*Xylogl.*) *tuberiformis*: On *Hevea brasiliensis* in Singapore, 1173.
- Xyleborus dispar*, On Fruit Trees, and *X. xylographus*; On *Quercus Gerryana* and *Pseudotsuga taxifolia*, in Oregon, 114.
- Xylina* spp (Green Fruit Worms); On Apple, Peach, Pear and Plum in Ontario, 247.
- "YAM" (*Dioscorea*): *Bagnisiopsis Dioscoreae*, 1304; *Paleopus dioscoreae*, 936.
- Yellow Leaf Spot. (*Cercospora Kopkei*); on Sugar Cane, 1057.
- Yellow Stripe Disease, On Sugar Cane, 1057.
- Yellowhead Fireworm, (*Peronea minima*), 495.
- "Yellowing" of Flax Seedlings, 1305.
- Yellows (Yellow Sides) (*Fusarium conglutinans*); Cultivated Cruciferae, 594.

- “Yerba de don Carlos” Johnson “Zigzag” (*Porthetria dispar*). 1433.  
 Grass or Canuela (*Sorghum halepense*), Weed in Porto Rico, 1430. *Zizyphus*: *Z. Spina-Christi*: *Aphis zizyphi* in Egypt, 487. *Zizyphus* sp., *Cero-plastodes cajani* and *Pulvinaria burkelli*, in Coimbatore, 242.  
*ZANTHOXYLUM*: *Helicobasidium Tanakae* in Japan. 705. Zululand: Coccids introduced in 1917, 244.  
 Zanzibar: Coccidae, 242. *Zythia Rabiei*, 1177.

## CONTENTS

### FIRST PART: ORIGINAL ARTICLES.

E. AROSENIUS, The Forest Industry in Sweden . . . . . Page 1

### SECOND PART: ABSTRACTS.

## AGRICULTURAL INTELLIGENCE.

### I. GENERAL INFORMATION.

LEGISLATIVE AND ADMINISTRATIVE MEASURES. — 1. International Yearbook of Agricultural Legislation, 7th. Year (1916).

RURAL HYGIENE. — 2. A Biological Analysis of Pellagra-Producing Diets: 1) The Dietary Properties of Mixtures of Maize Kernels and Beans. — 3. War Bread (Unsalted Lime Bread). — 4. The Nutritive Value of Soy Beans.

EXPERIMENTAL AND ANALYTICAL WORK. — 5. Recent Investigations and Observations Made at the Imperial Institute (London).

### II. — CROPS AND CULTIVATION.

#### a) GENERAL.

SOIL PHYSICS, CHEMISTRY AND MICROBIOLOGY. — 6. On the Origin of "Terra Rossa" (Red Soil) in Italy. — 7. Adsorption by Soils. — 8. Studies on the Organic matter of the Soil of the United States.

PERMANENT IMPROVEMENTS: DRAINAGE AND IRRIGATION. — 9. Construction and Use of Farm Weirs for Measuring Small Streams of Irrigation Water, in U. S. A.

TILLAGE AND METHODS OF CULTIVATION. — 10. Electrocultural Experiments in Great Britain and France. — 11. The Cultural Methods Applied to Winter Wheat in the Great Plains Area, U. S. A. — 12. Method of Rye-Growing in Uncultivated Rice-Fields, in Italy. — 13. Improved Method of Sugar Cane Cultivation.

MANURES AND MANURING. — 14. The International Trade in Fertilisers and Chemical Products Employed in Agriculture. — 15. The Fertilising Value of some Household Wastes. — 16. Fertilising Value of Waste Cabbage Leaves, in Holland. — 17. Fertilising Value of Cider Residues. — 18. Awards for the Location of Workable Phosphatic Deposits, in Germany. — 19. The Collection of Kelp in the United States for Potash Production. — 20. 30.20 % Potassium Salt as a Fertiliser. — 21. The Effect of Different Methods of Inoculation on the Yields and Protein Content of Alfalfa and Sweet Clover.

AGRICULTURAL BOTANY, CHEMISTRY AND PHYSIOLOGY OF PLANTS. — 22. *Isopyrum fumarioides*, a New Hydrocyanic Acid-Containing Plant. — 23. The Influence of Aeration of the Nutrient Solution in Water Culture Experiments; Remarks on the Water Culture Method. — 24. Researches on the Pigmentation of the Ear of Wheat. — 25. The Viability of the Seeds of *Raphanus sativus* L. as Affected by High Temperatures and Water Content. — 26. The Action of Overhead Electric Discharges on Oats and Clover.

INTERNAT. INST. OF AGRIC., *Internat. Review of Science and Practice of Agriculture*, Year IX, No. 1. Rome, Jan., 1918.

- PLANT BREEDING.** — 27. Reversible Transformability of Allelomorphs in Rice in Japan. — 28. Selection of Sorghum in Queensland, Australia. — 29. Researches on the 35 Factors Determining the Various Characters of the Genus *Pisum*, in the United States. — 30. The Indirect Effects of Certain Selections in Breeding Indian Corn. — 31. "Quality", a New Variety of Strawberry. — 32. Hybridisation Experiments: Between Species of *Dolichos*; Between Species of *Phaseolus*; Between the Genera *Dolichos* and *Phaseolus*. — 33. The Selection of Cotton for Resistance to Black Scale, in St. Vincent, East Indies.
- CEREAL AND PULSE CROPS.** — 34. Results of the Enquiry of the Office of Agricultural Information of the French Ministry of Agriculture on Manitoba Wheat. — 35. Results of the Cultivation of the Carlotta Strampelli Hybrid Wheat in Rice Fields in Italy. — 36. Trials of Different Methods for the Cultivation of Winter Wheat, in the Great Plains Area, U. S. A. — 37. Rye-Growing in Uncultivated Rice-Fields, in Italy.
- FIBRE CROPS.** — 38. Various Fibres Examined at the Imperial Institute, London. — 39. Flax Cultivation Trials in Egypt. — 40. Cotton Growing in Australia. — 41. New Paper-Making Materials Examined at the Imperial Institute, London.
- CROPS YIELDING OILS, DYES AND TANNINS.** — 42. *Ricinodendron Rautaneni*, An Oil-Yielding Euphorbiaceous Plant of the South-African Veldt. — 43. New Oil Seeds from American Palms. — 44. The Indigenous Tan and Dye-Producing Plants of New Zealand.
- RUBBER, GUM AND RESIN PLANTS.** — 45. *Melanorrhoea usitata*, a Plant from Burma and Siam producing a Black Lacquer.
- SUGAR CROPS.** — 46. Sugar Cane Cultivation and the Manufacture of Sugar in the Republic of Salvador, Central America.
- STIMULANT, AROMATIC, NARCOTIC AND MEDICINAL PLANTS.** — 47. *Capparis albitrunca*, a South African Plant Furnishing a Coffee Substitute. — 48. Production of Santal Oil in Mysore, British India. — 49. Tobacco Growing in Ireland (The Experiments in 1916). — 50. Tobacco from Northern Nigeria.
- HORTICULTURE.** — 51. The Leguminosae *Dolichos melanophthalmus* and *D. sesquipedalis* as Vegetables in Italy. — 52. A Simple Method for Forcing Rhubarb in the open air.
- FORESTRY.** — 53. The Work of the Philippine Bureau of Forestry.

### III. — LIVE STOCK AND BREEDING.

#### a) GENERAL.

- HYGIENE.** — 54. Studies on Fagopyrismus and Similar Affections in Canada. — 55. Eradicating Tall Larkspur on Cattle Ranges in the U. S. National Forests. — 56. The Properties of the Serum of Animals Hyperimmunised against Glanders, and the Choice of Animals for the Preparation of Such Serum Rich in Suitable Antibodies. — 57. Endoglobular Parasites Causing Diseases of Animals in Russian Turkestan. — 58. Notes in Regard to Bots, *Gastrophilus* spp. — 59. Observations on a Contagious Camel Disease Called "Jhooling" in British India. — 60. The Mortality of Rabbits in Wet Years in Consequence of Coccidiosis. — 61. Intestinal Parasites of Poultry, Their Prevention and Treatment.
- FEEDS AND FEEDING.** — 62. Feeding Studies: The Causes of the Dietary Insufficiency of Certain Rations. — 63. On the Impossibility of Watering the Milk by giving Large Quantities of Water to the Cow. — 64. Methods for Approximating the Relative Toxicity of Cottonseed Products. — 65. Food Value of the Waste Leaves of Different Varieties of Cabbage; Investigations in Holland. — 66. Acorns and Beechnuts as Food for Cattle. — 67. The Pulpy Mesocarp of the Fruit of *Ricinodendron Rautaneni* as a Cattle Food. — 68. The Value of Cider Apples, Perry Pears and their Respective Pomace as Food for Farm Stock.
- BREEDING.** — 69. Inheritance of Coat Colour in Swine; Experiments in the United States.

#### b) SPECIAL.

- HORSES.** — 70. The "Beirao" Horse in Portugal.
- CATTLE.** — 71. Milking by Machinery.
- POULTRY.** — 72. Poultry Feeding Tests in New Zealand. — 73. Turkey Rearing in Italy.
- SILK CULTURE.** — 74. Transmission of Richness of Silk and Hardiness in Crossing Silkworms. — 75. The Appearance of "Accidental Bivoltins" in Univoltin Breeds of the Silkworm.

- 76. Methods of Identifying Silkworm Eggs Made Bivoltin by the Action of Hydrochloric Acid; Investigations in Italy. — 77. "Akino-nogeshi" (*Lactuca brevirostris*), A New Silkworm Food Recently Discovered in Japan.
- FISH CULTURE. — 78. Carp-Breeding in Transplanted Rice Fields; Experiments at Vercelli, Italy.
- OTHER LIVE STOCK. — 79. The Amazon Turtle as a Producer of Eggs, Meat and Fish.

#### IV. — FARM ENGINEERING.

- AGRICULTURAL MACHINERY AND IMPLEMENTS. — 80. The Tractor in Relation to the Farm and Its Machinery. — 81. Machine Cultivation Tests at Noisy-Le-Grand, France. — 82. Machine Cultivation Tests at Bourges, France, in 1917. — 83. The Cost of Fuel used by Tractors for Ploughing, in Canada. — 84. The "Motoculteur", Built by the "Société La Motoculture Française". — 85. Howard's "Imperial" Disc Harrow. — 86. Mower for Gathering Kelp, in the United States. — 87. The Baldwin Standing Grain Thresher. — 88. The Rebuffel "Olive Gleaner". — 89. The "Alpha" apparatus for the Recovery of Metallic Objects in the Soil. — 90. Review of Patents.

#### V. — RURAL ECONOMICS

91. The Milk Producer's Problem in the United States. — 92. Economic Relations between the Tractor and the Farm.

#### VI. — AGRICULTURAL INDUSTRIES.

- INDUSTRIES DEPENDING ON PLANT PRODUCTS. — 93. Methods for Determining the Adulteration of Wines. — 94. The Use of Horse-Chestnuts for the Production of Alcohol. — 95. Utilisation of Acorns by Alcoholic Fermentation. — 96. Unsalted Lime Bread. — 97. The Problem of Sugar Manufacturing in India. — 98. The Manufacture of Sugar in the Republic of Salvador. — 99. The Utilisation of Grape Residues as Fuel.
- AGRICULTURAL PRODUCTS. — 100. Celery Storage Experiments. — 101. The Cost of Cattle Foods in the United States, from 1915 to 1917.

#### PLANT DISEASES.

##### III. — DISEASES DUE TO FUNGI, BACTERIA AND OTHER

##### LOWER PLANTS.

- GENERAL. — 102. New Japanese Fungi. — 103. New or Noteworthy North American Fungi.
- RESISTANT PLANTS. — 104. Rust Resistant Manitoba Wheat, in France. — 105. Vines Offering a Relative Resistance to Mildew.
- MEANS OF PREVENTION AND CONTROL. — 106. Patents for the Control of Diseases and Pests of Plants.
- DISEASES OF VARIOUS CROPS. — 107. Observations on Hemp Mildew (*Peronospora maculata*) in Italy. — 108. The "Irish Cold" and "Broad Leaf Burley" Varieties of Tobacco Attacked by *Thielavia basicola*, in Ireland. — 109. Black Rot Disease of Tea. — 110. A Disease of the Hemlock Tree.

##### IV. — WEEDS AND PARASITIC HOVERING PLANTS.

111. The Destruction of Weed Seeds by Carp, in Ricefields. — 112. The Extermination of Tall Larkspur (*Delphinium exaltatum*), a Poisonous Weed of Cattle Ranges in the U. S. National Forests. — 113. The Control of "Cogon Grass" (*Imperata exaltata*), a Grass Favouring the Incubation of Locusts.

## V.—INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

GENERAL. — 114. Scolytid Beetles Observed in Oregon (United States). — 115. *Sphinx convolvuli* in England in the Autumn of 1917. — 116. On the Parthenogenetic Reproduction of *Otiorrhynchus sulcatus*, a Coleopteron Injurious to the Vine, in France.

RESISTANT PLANTS. — 117. A Note on Resistance to Black Scale in Cotton.

MEANS OF PREVENTION AND CONTROL. — 118. Natural Enemies of *Chrysomphalus dictyospermi*, a Coccid Injurious to Citrus. — 119. *Phora fasciata*, a Dipterous Parasite of the Coleopteron *Coccinella septempunctata*, in France. — 120. *Sycosoter lavagnei* n. g. and n. sp., a Hymenopterous Parasite of the Coleopteron *Hipobarus ficus*, Injurious to the Fig Tree in France.

INSECTS, ETC., INJURIOUS TO VARIOUS CROPS. — 121. *Phytoecia cylindrica*, a Coleopteron Injurious to Carrots, in Sweden. — 122. *Rhagoletis pomonella*, the Apple Maggot, or Railroad Worm, An Injurious Dipteran Recorded for the First Time in British Columbia, Canada. — 123. *Stomacoccus platani* n. gen. and n. sp., a Coccid Observed on *Platanus racemosa* in California. — 124. Cynipidae Observed on *Castanopsis* spp. and *Quercus* spp. in America.

The Bureau assumes no responsibility with regard to the opinions and the results of experiments outlined in the Bulletin.

The Editor's notes are marked (Ed.).

*In quoting articles, please mention this REVIEW.*

## CONTENTS

### ABSTRACTS.

## AGRICULTURAL INTELLIGENCE.

### I. GENERAL INFORMATION.

- RURAL HYGIENE. — 125. The Distribution in Wheat, Rice and Maize Grains of the Substance, the Deficiency of which in a Diet causes Polyneuritis in Birds and Beri-Beri in Man. — 126. Some Remarks on Macedonian Anopheles. — 127. Agricultural Education in the United States.

### II. — CROPS AND CULTIVATION.

#### a) GENERAL.

- SOIL PHYSICS, CHEMISTRY AND MICROBIOLOGY. — 128 The Relation of Movement of Water in a Soil to its Hygroscopicity and Initial Moisture. — 129. Further Studies on the Nitric Nitrogen Content of the County Rock. — 130. Absorption and Other Modifications of Certain Fertilising or Anti-cryptogamic Compounds in Various Natural and Artificial Soils. — 131. Relation of the Transformation and Distribution of Soil Nitrogen to the Nutrition of Citrus Plants. — 132. Vegetation on Swamps and Marshes as a Indicator of the Quality of Peat Soil for Cultivation.
- PERMANENT IMPROVEMENTS: DRAINAGE AND IRRIGATION. — 133. Practical Information for Beginners in Irrigation. — 134. Irrigation of Semiarid Soils by Means of Wind Engines in U. S. A. — 135. Citrus Irrigation in California, U. S. A.
- MANURES AND MANURING. — 136. The Value of Coconut Poonac as Manures. — 137. Saltpetre: Its Origin and Extraction in India.

#### b) SPECIAL.

- AGRICULTURAL BOTANY, CHEMISTRY AND PHYSIOLOGY OF PLANTS. — 138. Inventory of Plants and Seeds Imported by the Office of Foreign Seed and Plant Introduction During the Period from April 1 to June 30, 1914. — 139. The Effect of Different Rotation Systems and Fertilisers on the Protein Content of Oats. — 140. The Composition of Grain Sorghum. — 141. The Action of the Constituents of the Ash on the Life of Plants. — 142. The Effect of Greenhouse Temperatures on the Growth of Cereals. — 143. The Selection of Cereals in Sweden and the Increased Production thus Caused. — 144. Linked Quantitative Characters in Wheat Crosses. — 145. Selection of "Kanred", a New Wheat Variety in Kansas, U. S. A. — 146. Studies on the Contamination of the Pollen of Rye with the Help of "Indicator Plants" in Sweden. — 147. Inheritance of Endosperm Colour in Maize. — 148. The Relation of Cob to Other Ear Characters in Maize. — 149. On Abnormal Ears of Maize Obtained from Seed Treated with Copper. — 150. Correlations between the Chemical and Morphological Characters of Sorghum. — 151. An Interesting Bud Variation in the Duchess Apple. — 152. A Bottle Necked Lemon.
- INTERNAT. INST. OF AGRIC., *Internat. Review of Science and Practice of Agriculture*, Year IX, No. II, Rome, Feb., 1918.

- CEREAL AND PULSE CROPS. — 153. Cereal Cultural Experiments made in 1916 at the Agricultural Station of Flahult, Sweden. — 154. Increased Production of Cereals in Sweden. — 155. The Colour Classification of Wheat. — 156. The Effect of Sodium Nitrate Applied at Different Stages of Growth on the Yield, Composition and Quality of Wheat. — 157. Experiments with Wheats at Verrières, Seine-et-Oise, France. — 158. Wheat Growing in Tuscany. — 159. "Kanred", a New Wheat for Kansas. — 160. Maize in Madagascar. — 161. Transplanting in the Control of "Wild" Rice in Italy.
- STARCH CROPS. — 162. Tuber and Root Cultivation Trials made in 1916 at the Agricultural Station of Flahult, Sweden.
- FORAGE CROPS, MEADOWS AND PASTURES. — 163. The Cultivation of Alfalfa in the Oasis of Tripoli. — 164. An Annual Variety of *Melilotus alba*. — 165. The *Eragrostis* of the Argentine and Uruguay: Their Value as Fodder Plants. — 166. Important Range Plants: Their Life History and Forage Value. — 167. Composition and Improvement of the South-Western Ranges of the United States. — 168. Influence of the Time of Cutting on the Amount and Composition of the Hay Produced.
- FIBRE CROPS. — 169. Bates "Big Boll", an American Variety of Cotton, Produced in Sicily. — 170. The *Ailanthus* (*Ailanthus glandulosa*) as a Paper-Yielding Plant.
- PLANTS YIELDING OILS. — 171. *Plukenetia conophora* ("Ngart") a New Oil Plant of the Cameroons.
- SUGAR CROPS. — 172. The Importance of Sweet Sorghum.
- FRUIT GROWING. — 173. Relation of the Transformation and Distribution of Soil Nitrogen to the Nutrition of Citrus Plants.
- FORESTRY. — 174. The Teak Trade of Siam.

### III. — LIVE STOCK AND BREEDING.

#### a) GENERAL.

- HYGIENE. — 175. Reaction Produced by the Intra-Palpebral Injection of Mallein. — 176. The Intra-Palpebral Reaction in the Diagnosis of Epizootic Lymphangitis. — 177. The Treatment of Epizootic Lymphangitis by Means of the Autolysed Extract of Yeast. — 178. Leucocytotherapy or Aseptic Pyotherapy; Its Use in Certain Cases of Equine Lymphangitis. — 179. The Poisoning of a Horse Caused by Eating *Paspalum distichum* Parasitised by *Ustilagopsis deliquescens*. — 180. Study of *Bacterium Pullorum* Infection.
- ANATOMY AND PHYSIOLOGY: GENERALITIES. — 181. Studies on the Duration of Life: Temperature Coefficients and Influencing Factors. — 182. Physiological Effect on Growth and Reproduction of Rations Balanced from Restricted Sources. — 183. On the So-Called Specificity of the Abderhalden Reaction.
- FEEDS AND FEEDING. — 184. Influence of the Date of Cutting on the Food Value of Hay; Experiments carried out in Denmark. — 185. The Feeding Value of the *Eragrostis* of the Argentine. — 186. The Insufficiency of Maize as a Source of Protein and Ash for Growing Animals. — 187. The Effect of Feeding Calcium Chloride to Domestic Animals.

#### b) SPECIAL.

- CATTLE. — 188. Increased Cattle Production on South-Western Ranges of the United States. — 189. The Awankari Cattle Herd of the Peshawar Agricultural Station in the North-West Frontier Province of India.
- SHEEP. — 190. The New Zealand Sheep Returns in 1917 and the Progress of Crossbreeding in New South Wales.
- PIGS. — 191. The Importance of Hogs for the Meat and Hides Supply.
- BEE KEEPING. — 192. "Le Sughere" Hive with Cork Frames. — 193. The Cotton Plant as a Honey-Yielding Plant.
- SERICULTURE. — 194. Comparative Research on the Value of the Electrical and Chemical Treatment of Silkworm Eggs. — 195. Selection by Phototaxy of Newly-Hatched Silk-

worm Larvac with Regard to their Strength. — 196. Studies on the Process of Digestion in Silkworm Larvac. — 197. On Natural Parthenogenesis in Various Breeds and Varieties of *Bombyx mori*. — 198. Note on Sericulture in Madagascar.

#### IV. — FARM ENGINEERING.

AGRICULTURAL MACHINERY AND IMPLEMENTS. — 199. Tractor Trials in Scotland in 1917. — 200. Ploughing and Harrowing with a Tractor. — 201. Harvesting with a Tractor. — 202. The Mailliet Field and Vineyard Tilling Machine. — 203. The "Kardell 4 in 1" Tractor. — 204. The "Eros" Tractor Plough. — 205. The W. A. Wood Motor-driven Binder. — 206. The "Balbo-Bertone" Motor Rice-Harvester. — 207. The Use of Wind Engines for Irrigating Semiarid Soils in the Western United States. — 208. The Marcel Landrin Non-Slip Wheel. — 209. Industrial Alcohol in South Africa. — 210. Review of Patents.

#### V. — RURAL ECONOMICS.

211. Value to Farm Families in the United States of Food, Fuel and the Use of House.

#### VI. — AGRICULTURAL INDUSTRIES.

INDUSTRIES DEPENDING ON PLANT PRODUCTS. — 212. The Composition of the Fixed Acidity of Sound and Diseased Wines. — 213. Contribution to the Study of Alcoholic Ferments. — 214. Contribution to the Study of the Alcohols of Cider. — 215. The Production of War Alcohol with Perry Pears. — 216. On Chalk Bread. — 217. Milling and Baking Tests of the New Wheat "Kaured", in Kansas, U. S. A. — 218. The Cotton Industry in China. — 219. Paper Making with *Ailanthus* Wood. — 220. Industrial Uses of Sweet Sorghum (Colouring Matter from the Glumes, etc.).

INDUSTRIES DEPENDING ON ANIMAL PRODUCTS. — 221. Investigations into the Proteolytic Activity of Lactic Ferments. — III. The Influence of the Method of Milk Sterilisation; IV. Lacto-culture in the Selection of Lactic Proteolytic Ferments. — 222. The Dairying Industry in South Africa. — 223. Photographic Analysis of Dried or Fresh Eggs. — 224. Dried Eggs. — 225. Production and Use of Pigskin.

AGRICULTURAL PRODUCTS. PRESERVING, PACKING, TRANSPORT, TRADE. — 226. The Handling and Storage of Spring Wheat. — 227. Substitutes for Tin Cans.

#### PLANT DISEASES.

##### III. — DISEASES DUE TO FUNGI, BACTERIA AND OTHER

##### LOWER PLANTS.

GENERAL. — 228. Fungi from Tropical Africa, California, and New Zealand.

RESISTANT PLANTS. — 229. Selected Danish Barleys Resistant to *Ustilago Hordei*, *U. nuda* and *Septoria graminum*, Introduced into the United States of America. — 230. A Rust-resistant, Danish *Festuca elatior*, Introduced into the United States of America. — 231. "New Era", a New Zealand Potato Resistant to Mildew. — 232. On Forms of the Hop (*Humulus Lupulus* L.) Resistant to Mildew (*Sphaerotheca humuli* D. C. Burr). — 233. "K'nei li tzu", a Chinese Chestnut Resistant to the "Ink Disease", Introduced into the United States of America.

MEANS OF PREVENTION AND CONTROL. — 234. Patents for the Control of Diseases and Pests of Plants.

DISEASES OF VARIOUS CROPS. — 235. Diseases and Pests of Lucerne in the Oasis of Tripoli. — 236. The South American Hevea Leaf Disease in Trinidad. — 237. Endrot of Cranberries. — 238. Watermelon Diseases in U. S. A.

## IV. — WEEDS AND PARASITIC HORVERING PLANTS.

239. *Kennedya rubicunda*, a Leguminous Plant Injurious to Forest Trees in New South Wales.  
— 240. Methods for the Control of "Wild Rice" in Italian Ricefields.

## V. — INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

- GENERAL. — 241. Observations on Animal Pests of Cultivated Plants, Made in Sweden from 1912 to 1916. — 242. Scale Insects (*Coccidae*) from Asia, Africa, America and Oceania. — 243. A List of Uganda Coccidae, their Food-Plants and Natural Enemies. — 244. The Status of Introduced Coccids in South Africa in 1917. — 245. The Fluted Scale (*Icerya purchasi*).  
INSECTS, ETC., INJURIOUS TO VARIOUS CROPS. — 246. Observations on *Lepidiotia frenchi*, Black, a Sugar Cane Pest in Queensland. — 247. Common Pests of Fruit Trees in Ontario, Canada. — 248. Three-lined Fig Borer. — 249. *Oscinnsoma discretum*, a Dipteron Observed in the Fruit of Wild Figs, in Italy.

The Bureau assumes no responsibility with regard to the opinions and the results of experiments outlined in this Review.

The Editor's notes are marked (Ed.).

*In quoting articles, please mention this REVIEW.*

## CONTENTS

-----

### ABSTRACTS.

### AGRICULTURAL INTELLIGENCE.

#### I. — GENERAL INFORMATION.

DEVELOPMENT OF AGRICULTURE IN DIFFERENT COUNTRIES. — 250. The Agricultural Wealth of the New Hebrides.

RURAL HYGIENE. — 251. *Gambusia affinis*, a Small Fish Very Useful for the Destruction of Mosquito Larvae. — 252. The Digestibility of the Dasheen. — 253. Hygienic Disadvantages of Using Lime in Breadmaking.

EXPERIMENTAL AND ANALYTICAL WORK. — 254. Studies and Investigations at the Imperial Institute, London. — 255. Electric Stimulation of Crops.

#### II. — CROPS AND CULTIVATION.

##### a) GENERAL.

AGRICULTURAL METEOROLOGY. — 256. The Problem of Agricultural Meteorology. — 257. The Relation of Winter Temperature to the Distribution of Winter and Spring Grain in the United States: Why Cereals Winterkill.

SOIL PHYSICS, CHEMISTRY AND MICROBIOLOGY. — 258. Effect of Decomposing Organic Matter on the Solubility of certain Inorganic Constituents of the Soil. — 259. The Proof of Microbial Agency in the Chemical Transformations of Soil. — 260. The Decomposition of Soil Protein Substances through the Action of Bacteria.

PERMANENT IMPROVEMENTS: DRAINAGE AND IRRIGATION. — 261. Irrigation of Orchards in U. S. A. — 262. Irrigation with Pumped Water in Montana, U. S. A.

MANURES AND MANURING. — 263. The Influence of Fineness of Division of Pulverised Limestone on Crop Yield as well as the Chemical and Bacteriological Factors in Soil Fertility. — 264. Fermentations of Manure Treated with Sulphur and Sulphates: Changes in Nitrogen and Phosphorus Content. — 265. Garbage Tankage, its Composition: The Availability of its Nitrogen and its Use as a Fertiliser. — 266. Effect of Three Annual Applications of Boron on Wheat.

##### b) SPECIAL.

AGRICULTURAL BOTANY, CHEMISTRY AND PHYSIOLOGY OF PLANTS. — 267. Occurrence of Manganese in Insect Flower Stems. — 268. The Proteins of the Peanut, *Arachis hypogaea*. The Distribution of the Basic Nitrogen in the Globulins Arachin and Conarachin. — 269. Sedoheptose, a New Sugar from *Sedum spectabile*. — 270. Influence of Hydrogen-Ion Concentration of Medium on the Reproduction of Alfalfa Bacteria. — 271. Influence of Position of Grain in the Cob on the Growth of Maize Seedlings. — 272. Graft Hybrids Observed on Olive and Maple Trees in Italy.

INTERNAT. INST. OF AGRIC. *Internat. Review of Science and Practice of Agriculture*, Year IX, No. III. Rome, March, 1918.

- PLANT BREEDING.—273. The Lulea Branch of the Svalöf Station, North Sweden.—274. Experiments in Field Technic in Rod Row Tests.—275. Correlations Observed in Continuously-Cropped Barley, in U. S. A.—276. A Method for Determining the Percentage of Self-Pollination in Maize.—277. The Relation of the Vigour of the Maize Plant to Yield.—278. Correlations between Ear Characters and Yield in Maize.—279. Breeding Sweet Corn Resistant to the Corn Earworm.—280. Correlations Observed in Maize Grains, in U. S. A.—281. Inheritance of Abbreviation of Growth in the Cultivated Carrot and Beet.—282. The Selection of Some Varieties of Swede Resistant to *Plasmiodiophora Brassicae*, in Denmark.—283. Flaxwilt: A Study of the Nature and Inheritance of Wilt Resistance.—284. Selection of Pea-seed.—285. Asparagus Selection in Massachusetts, U. S. A.—286. Hybrid Chestnuts in the United States.
- CEREAL AND PULSE CROPS.—287. Winter Wheats in the United States.—288. The Characters and Yields of Australian Wheats.—289. Some Effects of the Successive Cropping of Barley.—290. Studies on Maize in the United States: Influence of Position of Grain in the Cob on the Growth of Maize Seedlings.—291. The Worlds' Production of Rice.—292. The Utilisation of the Civet Bean (*Phaseolus vulgaris*), Cultivated in Madagascar.
- STARCH CROPS.—293. Winter Potato Growing in the African Sahel.—294. A "Water-Potato".
- FORAGE CROPS, MEADOWS AND PASTURES.—295. The Fodder Pulses of Bihar and Orissa: Meth, Bhiringi and Maahyem Kalay.—296. Grass Experiments at Hawkesbury Agricultural College, 1916-1917.
- FIBRE CROPS.—297. *Wrightia annamensis*, a Textile Fibre Plant of Indochina.
- HORTICULTURE.—298. Strawberry Growing in the United States.—299. Raspberry Culture.
- FRUIT GROWING.—300. Citrus Cultivation in Surinam.—301. The Nigerian Lime Tree (*Citrus medica* var. *acida*).—302. The Cultivation of the Pistachio Tree
- VINE GROWING.—303. Hybrid Bearers in 1917, in France.

### III. — LIVE STOCK AND BREEDING.

#### a) GENERAL.

- HYGIENE.—304. Screw-Worms and Other Maggots Affecting Animals.—305. The Cause and Prevention of Hairless Pigs, in the United States.—306. Iron as an Antidote to Cottonseed Meal Injury.—307. The Poisonous Properties of the Two-Grooved Milk Vetch (*Astragalus bisulcatus*).—308. Experiments on the Reported Poisonousness of Wild Melon Fruit.—309. Pyotherapy in the Treatment of Harness Wounds; Some Considerations on the Efficacy and Absolute Non-Specificity of Anticryptococcal Pyotherapy in the Horse.—310. The Curative Treatment of Epizootic Lymphangitis by Vaccinotherapy; Preparation of a Polyvalent Pyovaccine.—311. Pyotherapy in Epizootic Lymphangitis; Researches in Italy.—312. The Vitality of the Rinderpest Virus Outside the Animal Body under Natural Conditions.—313. Tuberculosis in Camels, in Egypt.
- ANATOMY AND PHYSIOLOGY: GENERALITIES.—314. Animal Calorimetry: The Interrelation between Diet and Body Condition and the Energy Production during Mechanical Work.
- FEEDS AND FEEDING.—315. The Effect of High Temperature on the Nutritive Value of Foods.—316. The Supplementary Dietary Relationship between Leaf and Seed as Contrasted with Combinations of Seed with Seed.
- STOCK RAISING: ORGANISATION AND ENCOURAGEMENT.—317. Indian Cattle Census.—318. Herd Book of the Argentine Rural Society.—319. The Stud Beef Cattle Breeders' Association of Australia.

#### b) SPECIAL.

- HORSES.—320. On the Use of Certain Marine Algae for Feeding Horses.

- CATTLE. — 321. Relation between the Weight of the Carcass and that of the Meat in Beef Cattle. — 322. A Statistical Study of Body Weights: Gains and Measurements of Steers During the Fattening Period. — 323. Influence of the Degree of Fatness of Cattle upon their Utilization of Feed. — 324. Breeders of Purebred Stock in Queensland — Beef and Dairy Cattle.
- SHEEP. — 325. Machine Sheep-Shearing in New Zealand.
- PIGS. — 326. Feeding Pigs on Kitchen Waste.
- SERICULTURE. — 327. New Silkworm Rearing Methods: The Acqua Small Trestle System and the Campbell Shelf System. — 328. On Some Cytological Data on the Phenomena of Parthenogenesis in the Silkworm.

#### IV. — FARM ENGINEERING.

- AGRICULTURAL MACHINERY AND IMPLEMENTS. — 329. The Work of a Tractor in Stony Soil. — 330. Cultivation Trials with a Moline Tractor, in Italy. — 331. The Dessaules Tractor. — 332. The Wyles Motor Plough. — 333. The Blanchard Double Brabant Windlass Plough. — 334. The Shubert Weed and Sprout Destroyer. — 335. Copra Driers. — 336. Investigations of Irrigation Pumping Plants in Montana, U. S. A. — 337. Review of Patents.

#### V. — RURAL ECONOMICS.

338. Size of Farm Business. — 339. Government Lands, Leased Lands and Alienated Lands in Australia. — 340. Machine Sheep-Shearing and Lack of Labour in New Zealand.

#### VI. — AGRICULTURAL INDUSTRIES.

- INDUSTRIES DEPENDING ON PLANT PRODUCTS. — 344. The Autolysis of Yeast and the Influence of its Products of Proteolysis on the Development of Yeast and Lactic Bacteria. — 342. The Milling and Baking Qualities of Australian Wheat. — 343. The Soluble Nitrogenous Matter as an Index of the Baking Quality of Flour — 344. The Use of Chalk in Breadmaking. — 345. Tapioca Starch Made in Rhodesia. — 346. Copra Driers in Jamaica. — 347. Wax from *Ceroxylon anducolum*. — 348. Notes on the Fibre of *Wrightia annamensis*.

#### PLANT DISEASES.

##### III. — DISEASES DUE TO FUNGI, BACTERIA AND OTHER LOWER PLANTS.

- GENERAL. — 349. Parasitic Fungi Collected in the Government of Podolia, Russia. — 350. Fungi of Southern China.
- RESISTANT PLANTS. — 351. Varieties of Swede Resistant to "Finger and Toe" (*Plasmiodiophora Brassicae*) in Denmark. — 352. Varieties of Flax Resistant to *Fusarium lini*, in the United States. — 353. Asparagus Resistant to Rust (*Puccinia Asparagi*) in Massachusetts, U. S. A. — 354. "Minnesota No. 1017", a Variety of Strawberry Little Resistant to Fungous Diseases, in the United States. — 355. Disease Resistant Direct Bearers; Observations in France, in 1917. — 356. Chestnut Hybrids Resistant to Canker (*Endothia parasitica*), in the United States.
- MEANS OF PREVENTION AND CONTROL. — 357. Patents for the Control of Diseases and Pests of Plants.
- DISEASES OF VARIOUS CROPS. — 358. *Bacillus atrosepticus*, a Cause of "Blackleg" in Potato in Lancashire, England. — 359. Notes on Downy Mildew of the Vine in Australia. —

360. Citrus Diseases in Surinam. — 361. *Blepharospora cambivora* n. gen. and n. sp., a Cause of "Ink Disease" in Chestnut Trees. — 362. *Diaporthe taleola*, an Ascomycete Injurious to Oaks, in Switzerland. — 363. *Chrysomyxa Abietis* in England and Scotland

#### IV. — WEEDS AND PARASITIC FLOWERING PLANTS.

364. — Devil's Fig (*Solanum largiflorum*), a New Weed in Queensland. — 365. A Machine for Destroying Weeds.

#### V. — INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

GENERAL. — 366. Biological Observations on Some Insects in the Department of Hérault, France. — 367. Life History of *Macrosiphum illinoisensis*, the Grapevine Aphis. — 368. *Lepidrum apetalum*, the Secondary Host of *Myzus cerasi* in Ontario, Canada.

RESISTANT PLANTS. — 369. Sweet Sorghum Varieties Resistant to the Corn Earworm, in the United States.

MEANS OF PREVENTION AND CONTROL. — 370. *Perezia mesnili* n. sp., a Protozoan Parasite of the Larvae of the Large White Cabbage Moth (*Pieris brassicae*) in France. — 371. *Hyperecteina polyphyllae* n. sp., a Dipterous Parasite of the Injurious Coleopteron *Polyphylla fullo*, in Russia.

INSECTS, ETC., INJURIOUS TO VARIOUS CROPS. — 372. *Cosmopteryx phaeogastra* n. sp. and *C. bambusae* n. sp., Microlepidoptera attacking Beans and Bamboo respectively, in India. — 373. Citrus Pests in Surinam. — 374. *Rhynchites baccus*, a Coleopteron Injurious to Apples, Apricots and Plums, in Sicily.

The Bureau assumes no responsibility with regard to the opinions and the results of experiments outlined in this Review.

The Editor's notes are marked (Ed.).

*In quoting articles, please mention this REVIEW.*

## CONTENTS

### ABSTRACTS.

### AGRICULTURAL INTELLIGENCE.

#### I. — GENERAL INFORMATION.

DEVELOPMENT OF AGRICULTURE IN DIFFERENT COUNTRIES. — 375. Agriculture in Crete. — 376. Agriculture and Forestry in Cyprus.

RURAL HYGIENE. — 377. A Biological Analysis of Pellagra-producing Diets. II. The Minimum Requirements of the Two Unidentified Dietary Factors for Maintenance as Contrasted with Growth. — 378. The Biological Efficiency of Potato Nitrogen. — 379. Food Value of Wholemeal and of 85 % Flour as Compared with White Flour. — 380. Toxic Bread and Flour; Detection and Estimation of Sapotoxins. — 381. The Prevention of Malta Fever by Active Immunisation of Animal Carriers. — 382. Loss of Power of Infection of Marsh Anopheles during Hibernation.

EXPERIMENTAL AND ANALYTICAL WORK. — 383. Electric Farming in the United States.

#### II. — CROPS AND CULTIVATION.

##### a) GENERAL.

AGRICULTURAL METEOROLOGY. — 384. Effect of Meteorological Factors on the Maturation of the Tissues and the Resistance to Cold of the Vine in U. S. A.

SOIL PHYSICS, CHEMISTRY AND MICROBIOLOGY. — 385. Vegetation as an Indicator of the Fertility of Sandy Pine Plains Soils in Northern Wisconsin. — 386. The Growth of Sheep Sorrel (*Rumex Acetosella*) in Calcareous and Dolomitic Media, in the United States — 387. Movement of Soluble Salts Through Soils. — 388. Total Nitrogen and Carbon in Cultivated Land and Land Abandoned to Grass and Weeds. — 389. The Effect of Different Salts on Ammonia Formation in the Soil. — 390. Aluminium as a Factor Influencing the Effect of Acid Soils on Different Crops. — 391. Nitrates and Nitrification in Relation to Cultural Practices and Plant Growth.

MANURES AND MANURING. — 392. Nitrification as a Measure of the Availability of Different Forms of Calcium Carbonate when Employed as Correctors of Soil Acidity. — 393. Changes Occurring During the Storage of Manure. — 394. The Problem of Potassium Salts in Italy. — 395. The Influence of Sodium Nitrate upon Nitrate Transformations in Soils with Special Reference to its Availability and that of other Nitrogenous Manures. — 396. Experiments on the Bacterisation of Peat for Soil Fertilising Purposes. 397. Fertiliser Applied to the Potato in Illinois, U.S.A.

PERMANENT IMPROVEMENTS, DRAINAGE AND IRRIGATION. — 398. Irrigation in the Island of Cyprus.

---

INTERNAT. INST. OF AGRIC. *Internat. Review of Science and Practice of Agriculture*, Year IX, No. IV, Rome, April, 1918.

## b) SPECIAL.

- AGRICULTURAL BOTANY, CHEMISTRY AND PHYSIOLOGY OF PLANTS. — 399. Studies on Inulin in Plants: I. Its Formation; II. The Changes it Undergoes in the Resting Tuber of the Jerusalem Artichoke. — 400. Studies on the Cyanogenetic Compounds of Sorghum. — 401. Analysis of Lamia Palm Nuts and Leaves. — 402. The Chemical Composition of the Potato Plant at Various Stages of Development. — 403. The Growth of Isolated Plant Embryos. — 404. Variations in the Development of Secondary Rootlets in Cereals.
- PLANT BREEDING. — 405. The Selection and Hybridisation of Cereals in Alaska, U.S.A. — 406. The Inheritance of Glume Length in *Triticum polonicum*. A Case of Zygotic Inhibition. — 407. Oat Selection by Pure Lines at the Agricultural Experiment Station of Maine, U.S.A. — 408. Genetic Study of the Awns of a Variety of Six-Rowed Barley. — 409 "Reggiano Maize", a New Variety of Early Dwarf Maize Obtained in Italy by Hybridisation and Selection. — 410. The Improvement of Cotton by Selection, in India. — 411. The Effect of Selection on "Kumpla" Cotton and on the Quality of Its Fibre, in India.
- CEREAL AND PULSE CROPS. — 412. Yields of Different Varieties of Maize in Illinois. — 413. A New Early Variety of Dwarf Maize, Obtained in the Province of Reggio-Emilia, Italy. — 414. Indo-Chinese Rice.
- STARCH CROPS. — 415. The Composition of the Potato Plant at Various Stages of Development. — 416. Methods of Applying Fertiliser to Sweet Potatoes.
- FORAGE CROPS, MEADOWS AND PASTURES. — 417. Grasses and Other Fodder Plants of Victoria, Australia. — 418. Bokkara or Sweet Clover (*Melilotus alba*) in New South Wales.
- FIBRE CROPS. — 419. The Selection of Kumpla Cotton in India. — 420. Ambhari or Deccan Hemp, *Hibiscus Cannabinus* L., in South Africa.
- OIL-YIELDING CROPS. — 421. Contribution to the Chemical Study of the Nuts of "Sangasanga" or *Ricinodendron africanum*.
- HORTICULTURE. — 422. Commercial Fruit Growing in Indiana.
- FRUIT GROWING. — 423. Methods of Cultivating Trees in Relation to Soil Nitrification.
- VINE GROWING. — 424. Extension of the Limits of Cultivation of the Vine by Means of Certain Hybrids. — 425. Vinifera Grapes in the State of New York, U. S. A. — 426. Vine Growing in Crete. — 427. Winter Injury of Grapes in Kentucky, U.S.A.
- FORESTRY. — 428. The Arboretum of M. P. de Villmorin at Pezanin (Saone-et-Loire, France), and the Results Obtained there. — 429. "Peh-Muh" and "Xun-Peh-Muh", Trees in Tonkin New to Science. — 430. The Forests of the Island of Cyprus. — 431. Fertility and Population of the Sandy Pine Plains of Northern Wisconsin, U.S.A.

## III. — LIVE STOCK AND BREEDING.

## a) GENERAL.

- HYGIENE. — 432. Experimental Feeding of Sheep with two Poison Plants: — Wild Indigo (*Sesbania luteola*) and Native Wild Tobacco (*Nicotiana glauca*), in New South Wales. — 433. Parasitic Nematodes in the Belgian Congo. — 434. The Culture of the Parasite of Epizootic Lymphangitis and the Experimental Production of the Disease in the Horse, in France. — 435. Immunisation of Goats against Malta Fever by Vaccination. — 436. Contagious Septicaemia of Swine in Morocco. — 437. Avian Blood Parasites of French Guiana. — 438. Chicken Pox in Poultry in Canada.
- ANATOMY AND PHYSIOLOGY: GENERALITIES. — 439. The Chemical Composition of the Placenta of the Cow. — 440. Foetal Athyrosis. A Study of the Iodine Requirement of the Pregnant Sow.
- FEEDS AND FEEDING. — 441. The Availability of the Energy of Food for Growth. — 442. The Feeding of Young Chicks on Grain Mixtures of High and Low Lysine Content. — 443. The Relative Value of Certain Proteins and Protein Concentrates as Supplements to Maize Gluten. — 444. The Nutritive Properties of Kaffin.

## b) SPECIAL.

- CATTLE. — 445. The Influence of the Stage of Gestation on the Composition and Properties of Milk. — 446. The Effect of Pepsin Whey on Calves.
- PIGS. — 447. Swine Management in U.S.A.
- POULTRY. — 448. Blood Fat in Domestic Fowls in Relation to Egg Production.
- SERICULTURE. — 449. Second Report on the Experiments carried out at Pusa to Improve the Mulberry Silk Industry.
- OTHER LIVE STOCK. — 450. Fresh-Water Mussels: Their Exploitation and Artificial Propagation in the Rivers of the United States.

## IV. — FARM ENGINEERING.

- AGRICULTURAL MACHINERY AND IMPLEMENTS. — 451. The Encouragement of Mechanical Cultivation in France. — 452. Mechanical Cultivation Tests at Rabat, Morocco. — 453. The Application of Electricity to Agriculture in France. — 454. Tractors in the United States. — 455. The Conversion of Automobiles into Tractors. — 456. Fuel Saving. — 457. Fire Prevention and Fire Fighting on the Farm, in U.S.A. — 458. Review of Patents.
- FARM BUILDINGS. — 459. The Construction of Poultry Houses in U.S.A.

## V. — RURAL ECONOMICS.

460. — Cost of Keeping Farm Horses and Cost of Horse Labour in the United States.

## VI. — AGRICULTURAL INDUSTRIES.

- INDUSTRIES DEPENDING ON PLANT PRODUCTS. — 461. New Method for the Separation and Estimation of Lactic, Succinic and Malic Acid in Wine. — 462. Alcoholic Fermentation of the Jerusalem Artichoke. — 463. Characteristics and Quality of Montana Grown Wheat. — 464. The Catalase Activity of American Wheat Flours. — 465. Brazilian Oilseeds — 466. Paper-Yielding Plants. — 467. Utilisation of the Red Dye Obtained from the Leaf-Sheaths and Stalks of Certain Varieties of Sorghum. — 468. A Study of Methods for Preparing Liquorice Extract. — 469. Berry Wax.
- INDUSTRIES DEPENDING ON PLANT PRODUCTS. — 470. Detection of Lime Used as a Neutralizer in Dairy Products. — 471. The Determination of Bacteria in Ice Cream. — 472. Chicago Dressed Carcase Contest of Cattle, Sheep and Hogs.
- AGRICULTURAL PRODUCTS: PRESERVING, PACKING, TRANSPORT, TRADE. — 473. The Colon-Acrogenes Groups from Silage. — 474. Preservation of the Roots of Jerusalem Artichoke. — 475. Cold Storage Butter.

## PLANT DISEASES.

III. — DISEASES DUE TO FUNGI, BACTERIA AND OTHER  
LOWER PLANTS.

- GENERAL. — 476. Fungi, Insects and Animals Injurious to Cultivated Plants in Norway in 1916. — 477. Fungi of Eritrea and Abyssinia.
- RESISTANT PLANTS. — 478. The Resistance of Peanuts to *Sclerotium Rolfsii*.
- DISEASES OF VARIOUS CROPS. — 479. On a Sudden Outbreak of Cotton Rust (*Æcidium Gossypii*), in Texas. — 480. Vegetable Parasites of the Cacao-Tree in the State of Bahia, Brazil. — 481. Diseases and Pests of the Onion, in Illinois, U.S.A. — 482. A Phyllosticta of the Royal Palm in Cuba. — 483. An Unidentified Fungus Injurious to the Conifer *Cedrus Deodara* in India.

## IV. — WEEDS AND PARASITIC FLOWERING PLANTS.

484. — Some Farm Weeds in Sindh, India.

## V. — INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

GENERAL. — 485. Observations on British Coccidae. — 486. Animal Pests of Cultivated Plants in Norway, in 1916. — 487. African Aphididae.

RESISTANT PLANTS. — 488. "4 F", a Variety of Cotton Resistant to Insect Attack in the Punjab, India.

MEANS OF PREVENTION AND CONTROL. — 489. The Control of Locusts in Cyprus. — 490. Patents for the Control of Plant Pests.

INSECTS, ETC., INJURIOUS TO VARIOUS CROPS. — 491. *Tylenchus penetrans* n. sp., a New Nematode Parasite of Cotton, Potatoes and Other Plants. — 492. Animal Pests of Onions, in Illinois. — 493. Insect and Vegetable Parasites of the Cacao-Tree in the State of Bahia, Brazil. — 494. *Euxoa excellens* Grt., a Little Known Cutworm in British Columbia. — 495. Insects Injurious to the Cranberry in the United States. — 496. Important Pecan Insect Pests and Their Control.

*In quoting articles, please mention this REVIEW.*

## CONTENTS

### FIRST PART: ORIGINAL ARTICLES.

W. A. N. ROBERTSON. — The Livé Stock Industry in Australia . . . . . page 530

### SECOND PART: ABSTRACTS.

## AGRICULTURAL INTELLIGENCE.

### I. — GENERAL INFORMATION.

DEVELOPMENT OF AGRICULTURE IN DIFFERENT COUNTRIES. — 497. Agricultural Development of British Guiana.

RURAL HYGIENE. — 498. The Organisation of the Rural Hygiene Service in Spain. — 499. Public Health Studies Concerning Cheese. — 500. The Digestibility and Utilization of Egg Proteins. — 501. The Vitamine Content of Brewer's Yeast.

### II. — CROPS AND CULTIVATION.

#### a) GENERAL.

AGRICULTURAL METEOROLOGY. — 502. The Effects of Meteorological Factors on the Growth and Yield of Rice in the Vercelli District, Piedmont, Italy. — 503. Plants Resistant to Adverse Meteorological Conditions Obtained by Selection.

SOIL PHYSICS, CHEMISTRY AND MICROBIOLOGY. — 504. New Experiments in Dry Farming in Italy. — 505. A Correlation Between Bacterial Activity and Lime Requirement in Soils.

PERMANENT IMPROVEMENT, DRAINAGE AND IRRIGATION. — 506. Drainage Ditching of Irrigated Lands in Colorado, U. S. A. — 507. Irrigation of Alfalfa in the United States.

MANURES AND MANURING. — 508. The Progress of the Nitrogen Industry. — 509. Spanish Mineral Products Employed in Agriculture. — 510. Fertilizers in Australia. — 511. Manganese Sulphate as a Catalytic Fertiliser for Sugar Beets.

#### b) SPECIAL.

AGRICULTURAL BOTANY, CHEMISTRY AND PHYSIOLOGY OF PLANTS. — 512. Cyanogenesis in Plants. Studies in *Tridens flavus* (Tall Red Top). — 513. Researches on Carotin and Its Possible Toxicity. — 514. The Origin of the Resins in the Pine. — 515. The Effect of One Growing Plant on Another. — 516. Action of Magnesium Salts on Wheat. — 517. Action of Sodium Compounds on Wheat. — 518. The Toxic Action of Soluble Aluminium Salts upon the Growth of the Rice Plant.

PLANT BREEDING. — 519. The Selection of Plants Resistant to Diseases, Animal Pests and Adverse Meteorological Conditions. — 520. Varieties of Egyptian Cotton Produced by Mutation. — 521. Variations in Eucalyptus Trees in Plantations; Eucalyptus Hybrids Observed Chiefly in Algeria.

INTERNAT. INST. OF AGRIC. *Internat. Review of Science and Practice of Agriculture*, Year IX, No. V. Rome, May, 1918.

- AGRICULTURAL SEEDS. — 522. The Production of Forage Plant Seeds in Denmark.  
 CEREAL AND PULSE CROPS. — 523. The Identification of Varieties of Barley.  
 FORAGE CROPS, MEADOWS AND PASTURES. — 524. Sorghums for Forage in South Dakota. —  
 525. *Medicago falcata*, a Yellow-Flowered Alfalfa.  
 CROPS YIELDING OILS, DYES AND TANNINS. — 526. Cultivation of the Castor-Oil Plant in  
 North America.  
 RUBBER, GUM AND RESIN PLANTS. — 527. Rubber in North Borneo.  
 SUGAR CROPS. — 528. Chemical and Biological Researches on Sugar Beets in Bohemia. —  
 529. Experiments on the Catalytic Fertilisation of Seed Sugar Beets with Manganese  
 Sulphate in Austria.  
 STIMULANT, AROMATIC, NARCOTIC AND MEDICINAL PLANTS. — 530. Cacao in the Dominican  
 Republic. — 531. Hop-Growing in Galicia, Spain.  
 FRUIT GROWING — 532. Results Obtained in Italy from the Sowing of Wild-Fig Seed. —  
 533. The Native Bananas of the Hawaiian Islands. — 534. The Mango in Porto Rico.  
 VINE GROWING. — 535. Direct Bearers: I. In the Department of the Isère; II. In the Depart-  
 ment of the Loire (France).  
 FORESTRY. — 536. The Red Spruce: Its Growth and Management in the United States. —  
 537. Forest Yield of Public Land in Spain. — 538. Timber of British Guiana. — 539. The  
 Galls of *Tamarix articulata* Vahl. — 540. Forest Fires in the United States in 1915.

### III. — LIVE STOCK AND BREEDING.

#### a) GENERAL.

- HYGIENE. — 541. The Chemical Composition of Lime-Sulphur Animal Dips. — 542. The Toxi-  
 city of Carotin. — 543. Studies in Blackleg (Symptomatic Anthrax) Immunization with  
 Special Reference to Blackleg Filtrate. — 544. On the Possibility of the Passage of Try-  
 panosomes into Milk.  
 ANATOMY AND PHYSIOLOGY: GENERALITIES. — 545. The Basal Catabolism of Cattle and Other  
 Species. — 546. Adenine and Guanine in Cow's Milk.  
 FEEDS AND FEEDING. — 547. The Nature of the Dietary Deficiencies of the Oat Kernel. —  
 548. Feeding Experiments on the Substitution of Protein by Definite Mixtures of Isolated  
 Amino-Acids. — 549. Fat Assimilation.

#### b) SPECIAL.

- CATTLE. — 550. The "Optimum Age" for Fattening Off Irish Bullocks.  
 POULTRY. — 551. Breeding Hens for Egg Production. — 552. The Behaviour of Chickens  
 Fed Rations Restricted to: — I) Cereal Grains; II) Wheat or Maize Kernel. — 553. Studies  
 on the Physiology of Reproduction in the Domestic Fowl.

### IV. — FARM ENGINEERING.

- AGRICULTURAL MACHINERY AND IMPLEMENTS. — 554. State Motorculture in England and Scot-  
 land. — 555. Agricultural Machinery in Italy. — 556. Energy Required in Cultivation. —  
 557. The Agricultural Tractor: Some Factors Governing the Design of a Small Tractor. —  
 558. Improvements of Agricultural Implements in India. — 559. Implements Used for  
 Cultivating Rice in India. — 560. The "Acrometer" — 561. Double Disc-Harrows for Me-  
 chanical Cultivation — 562. Harrows with Rotary Spades. — 563. The "Bucheronne",  
 a Machine for Felling and Sawing Coppice-Wood. — 564. The Austin Excavator for Drain-

age Ditching. — 565. The Use of Hydrogen for Driving Engines: Tests in Holland. — 566. Review of Patents.

## VI. — AGRICULTURAL INDUSTRIES.

INDUSTRIES DEPENDING ON PLANT PRODUCTS. — 567. The Passage of Wine over Fresh Lees. 568. The Alcoholic Fermentation of Banana Must. — 569. The Production of Alcohol from Algae. — 570. Sorghum or Dari, a New Substitute for Malt Used in Brewing. — 571. Microscopical Studies on Tomato Products. — 572. The Importance of Bacterial Action in Indigo Manufacture. — 573. The Use of *Imperata cylindrica* in Paper Making; Experiments in Italy.

INDUSTRIES DEPENDING ON ANIMAL PRODUCTS. — 574. Dairy Inspection in the United States. — 575. The Daily per Capita Consumption of Milk in the United States (Connecticut). — 576. Chemical Changes in the Souring of Milk. — 577. Studies on Goat's Milk. I. The Casein of Goat's Milk; II. The Soluble and Insoluble Compounds of Goat's Milk. — 578. A Comparison of the Composition of Cow's Milk, Goat's Milk and Human Milk. — 579. Pasteurization of Cream. — 580. Concerning Rancidity of Butter. — 581. Indole and Scatole in Cheese. — 582. Cheese Mites.

AGRICULTURAL PRODUCTS: PRESERVING, PACKING, TRANSPORT, TRADE. — 583. The Handling and Precooling of Florida Lettuce and Celery.

## PLANT DISEASES.

### II. — DISEASES NOT DUE TO PARASITES OR OF UNKNOWN ORIGIN.

584. Observations on the Damage Done to Trees by Tarring the Streets of Milan, Italy.

### III. — DISEASES DUE TO FUNGI, BACTERIA AND OTHER LOWER PLANTS.

GENERAL. — 585. Rusts and Smuts Collected in New Mexico in 1916. — 586. Brazilian Fungi. — 587. Fungi of the Philippine Islands. —

RESISTANT PLANTS. — 588. Plants Resistant to Diseases, Pests and Adverse Meteorological Conditions.

MEANS OF PREVENTION AND CONTROL. — 589. Mineral Anticryptogamic Compounds Produced in Spain. — 590. Comparison of the Effects of Copper Mixtures and Acid Mixtures on Mildew of the Vine. — 591. Patents for the Control of Diseases and Pests of Plants.

DISEASES OF VARIOUS CROPS. — 592. *Pseudomonas Tritici* n. sp., Injurious to Wheat in the Punjab. — 593. Bacterial Blight of Barley. — 594. Diseases of Cabbage in the United States. — 595. *Pseudomonas seminum* n. sp., a Bacterium Injurious to Peas, in England. — 596. *Verticillium albo-atrum*, a Hyphomycete Causing "Vissnes Juka" (Wilt) of Cucumber in Sweden. — 597. On "Verde-secco" of Fruit Trees in Apulia, Italy. — 598. *Monilia* sp., the Cause of a Specific Gummosis of the Apricot Tree in Italy. — 599. Treatment of *Fusicladium pirinum* var. *Eriobotryae*, Injurious to the Japanese Medlar Tree. — 600. The Tumours of the Cluster-Pine (*Pinus Pinaster*), in France. — 601. *Phyllactinia suffulta*, an Ascomycete Injurious to Common Oak, in Spain.

## V.—INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

GENERAL. — 602. Biological Observations on some Coleoptera of the Department of Hérault, France.

MEANS OF PREVENTION AND CONTROL. — 603. *Perezia legeri* n. sp., a Protozoan Parasite of the Larvae of the Large White Cabbage Moth (*Pieris Brassicae*).

INSECTS, ETC., INJURIOUS TO VARIOUS CROPS. — 604. *Leptocorisa varicornis*, a Weevil Injurious to Rice in Assam. — 605. Experiments on the Disinfection of Dwarf Beans Infested with *Acanthoscelides obtectus* and *Spermophagus subfasciatus*. — 606. Observations on *Acanthoscelides obtectus* (Bean Weevil), in Italy. — 607. *Hypothenemus ritchiei* n. sp., a New Scolytid Injurious to Dried Sweet Potatoes in Jamaica. — 608. A New Weevil Pest of Sweet Potatoes in Jamaica. — 609. Insect Parasites of the Cacao Tree and other Cultivated Plants in São Thomé. — 610. The Most Common Deformities Caused by Animals on Fruit Trees in Sicily. — 611. *Olethreutes variegana*, a Microlepidopteron Injurious to Fruit Trees, in Italy. — 612. The Campaign against the Codlin Moth (*Carpocapsa pomonella*) in Cyprus. — 613. Strong Lime-Sulphur Spraying against *Chrysomphalus dictyospermi*, a Coccid Injurious to Citrus. — 614. Observations on *Coelidodes ruber*, a Coleopteron Injurious to Hazel Trees in Italy. — 615. *Coleophora fuscedinella*, a Microlepidopteron Injurious to Birch and other Trees in Sweden.

The Bureau assumes no responsibility with regard to the opinions and the results of experiments outlined in this Review.

The Editor's notes are marked (Ed.).

## CONTENTS

### ABSTRACTS.

### AGRICULTURAL INTELLIGENCE.

#### I. — GENERAL INFORMATION.

- RURAL HYGENE. — 616. The Nutritive Value of Yeast, Polished Rice and White Bread as Determined by Experiments on Man. — 617. The Digestion of Aleurone Cells Incorporated in 85 % Bread: Experiments in France. — 618. Physiological and Pharmacological Studies on Coal Tar Colours. Experiments with Fat-Soluble Dyes. — 619. Copper in Certain White Wines, in Chocolate and in Beans.
- EXPERIMENTAL AND ANALYTICAL WORK. — 620. Report on the Agricultural Control Stations of Holland for the Year 1916-1917.

#### II. — CROPS AND CULTIVATION.

##### a) GENERAL.

- AGRICULTURAL METEOROLOGY. — 621. Method for Calculating the Length of the Growing Season at any Period of the Year and in any Locality. — 622. The Relation of Weather to the Amount of Cotton Ginned during Certain Phases of the Harvest.
- SOIL PHYSICS, CHEMISTRY AND MICROBIOLOGY. — 623. Researches on Certain "Soil Sickneses" in the Netherlands. — 624. Studies on Nitrification in Natural Soils and Its Importance from an Ecological Point of View, in Sweden.
- PERMANENT IMPROVEMENT, DRAINAGE AND IRRIGATION. — 625. Irrigation of Rice in California.
- MANURES AND MANURING. — 626. On Green Manures. — 627. Fertilizers in South Africa.

##### b) SPECIAL.

- AGRICULTURAL BOTANY, CHEMISTRY AND PHYSIOLOGY OF PLANTS. — 628. Plants Imported into the United States by the Bureau of Plant Industry of the Department of Agriculture during the Half-Year July 1 to December 31, 1917. — 629. The Separation of Autogenous and Added Hydrocyanic Acid from Certain Plant Tissues and its Disappearance during Maceration. — 630. The Direct Influence on the Stock of the Sap produced by the Scion, and the Action on the Plant of Acid Solutions Absorbed Directly. Experiments in Italy. — 631. The Influence of Acids on Germination. — 632. Some Effects of Organic Growth Promoting Substances (Auximones). — 633. Translocation of Seed Protein Reserves in the Growing Maize Seedling.
- PLANT BREEDING. — 634. The Origin of "Humpback" Wheat by Selection. — 635. Two New Varieties of Field Pea Obtained by Pure Line Selection, in Norway. — 636. Maternal In-
- INTERNAT. INST. OF AGRIC. *Internat. Review of Science and Practice of Agriculture*, Year IX, No. VI. Rome, June, 1918.

- heritance in the Soy Bean. — 637. Hybridisation Experiments between Different Varieties of the Cultivated and Wild Strawberry, in Alaska, U. S. A. — 638. Acclimatisation, Selection and Hybridisation Experiments with Fruit Trees in Alaska, U. S. A.
- AGRICULTURAL SEEDS. — 639. The Germination and Purity of Seeds in Alaska.
- CEREAL AND PULSE CROPS. — 640. Study on Two Spring Wheats: "Aurora" and "Blé des Alliés". — 641. Marquis Wheat. — 642. The Origin, Characteristics and Quality of Humpback Wheat.
- PLANTS YIELDING TANNIN. — 643. Plants Yielding Tannin, in India.
- RUBBER, GUM AND RESIN PLANTS. — 644. Venezuelan Production of Balata.
- SUGAR CROPS. — 645. The Nature of the Soil and Manuring as Factors Determining the Tendency of Beets to Bolt (Set Seed) the First Year. — 646. Experiments on the Cultivation of Sugar Beet in Sicily.
- HORTICULTURE. — 647. Varieties of Strawberry and their Culture in Indiana, U. S. A. — 648. Varieties and Cultivation of Raspberries, Blackberries, Gooseberries and Currants in Indiana, U. S. A.
- FRUIT GROWING. — 649. The Common Honey Bee as an Agent in Plum Pollination. — 650. The Selection and Acclimatisation of Fruit Trees in Alaska, U. S. A.
- VINE GROWING. — 651. Grafting Stock in Sicily: The Experimental and Demonstration Vineyards Attached to the Royal Nursery of American Vines at Marsala.
- FORESTRY. — 652. Humification and Nitrification in Forest Soils.

### III. — LIVE STOCK AND BREEDING.

#### a) GENERAL.

- HYGIENE. — 653. Studies in Forage Poisoning. — 654. The Toxic Action of *Thlaspi alliaceum* and the Active Principles of Some Poisonous or Suspected Cruciferac. — 655. Researches on the Malady "Trembles" or "Milk Sickness", caused by *Eupatorium ageatoides* in North Carolina, U. S. A. — 656. Investigations on the Etiology and Control of Infectious Abortion in Mares, in Kentucky, U. S. A.
- FEEDS AND FEEDING. — 657. The Amino-Acid Minimum for Maintenance and Growth, as Exemplified by Further Experiments with Lysine and Tryptophane. — 658. Influence of the Amino-Acid Content of the Diet on the Growth of Chickens. — 659. Studies on the Nutritive Deficiencies of Wheat and Grain Mixtures and the Pathological Conditions produced in Swine by their Use. — 660. The Stability of the Growth Promoting Substance in Butter-Fat. — 661. A Vitamine Favouring Growth, Isolated from the Pancreas of the Sheep. — 662. The Nature of the Dietary Deficiencies of the Wheat Embryo. — 663. Studies of Cotton-seed as Food. — 664. Test of Three Protein Concentrates and Two Leguminous Roughages in Milk Production. — 665. Feeding with Maize Silage and Ground Cotton Cake: Its Influence on the Composition and Quality of the Butter.

#### b) SPECIAL.

- CATTLE. — 666. The Role of Water in a Dairy Cow's Ration; Investigations made in U. S. A. — 667. The Influence of Parturition on the Composition and Properties of the Milk and Milk Fat of the Cow. — 668. Winter Steer Feeding in Indiana, U. S. A.
- SHEEP. — 669. Fattening Western Lambs in U. S. A.

- BEE KEEPING. — 670. The Wintering of Bees in Ontario, Canada. — 671. Bottini, Colantoni, "Subalpina" and "Sughera" Bee Hives. — 672. The Common Honey Bee as an Agent in Plum Pollination.
- SERICULTURE. — 673. Can the Action of Cold Decrease Mortality among Silkworms Suffering from "Flacherie"? — 674. On the Discovery of a Plant Suitable for Feeding Silkworms. — 675. Production of Silkworm Eggs of the Annual Breed, in Japan in 1917. — 676 Development of the Silkworm Industry in Cambodia.
- FISH CULTURE. — 677. The Raising of Leather-Carp and Black-Bass in Sologne, France.

#### IV. — FARM ENGINEERING.

- AGRICULTURAL MACHINERY AND IMPLEMENTS. — 678. British Agricultural Tractors. — 679. Ploughing with Government Tractors in England. — 680. The Use of Coal Gas for Ploughing Tractors. — 681. Ridger for Making Irrigation Levees. — 682. Review of Patents.

#### V. — RURAL ECONOMICS.

683. Organization of Ten Dairy Farms in the Bluegrass Region of Kentucky.

#### VI. — AGRICULTURAL INDUSTRIES.

- INDUSTRIES DEPENDING ON PLANT PRODUCTS. — 684. Wine Making with Foxy Grapes. — 685. Cupreous White Wines with Extreme Delayed Thickening. — 686. The Mycodermis of Wine. — 687. Cement Vats. — 688. A Method for the Separation of Protein from Non-Protein Nitrogen in Wheat Flour. — 689. The Milling Value of the Wheats "Aurore" and "Blé des Alliés". — 690. Milling and Bread-Making Tests with Humpback Wheat, in the U. S. A. — 691. A Comparison of Linseed Oil and Lumbang Oils as Paint Vehicles. — 692. The Use of *Bacillus feltineus* in Retting Various Textile Plants
- INDUSTRIES DEPENDING ON ANIMAL PRODUCTS. — 693. The Proteins of Cow's Milk — 694. On the Thermo-Resistance of Non-Sporogenous Bacteria in Milk. — 695. New Contribution to the Commercial Sterilisation of Milk. — 696. The Composition and Market Qualities of Butter when Corn Silage is Fed with Cottonseed Meal. — 697. The Determination of Fat in Certain Milk Products. — 698. Wool Studies: Washing Sheep Before Shearing; Time of Shearing. — 699. The Indian Hide and Leather Trade.
- AGRICULTURAL PRODUCTS: PRESERVING, PACKING, TRANSPORT, TRADE. — 700. The Refrigeration Plant of Lyndiane, Senegal. — 701. Enzyme Activity at the Temperature Maintained in Cold-Stores. — 702. Preserving Fish without Ice. — 703. The Supply of Canned Salmon in the United States.

#### PLANT DISEASES.

##### III. — DISEASES DUE TO FUNGI, BACTERIA AND OTHER LOWER PLANTS.

- GENERAL. — 704. Myxomycetes and Fungi of Ceylon. — 705. New Japanese Fungi. — 706. Fungi of the Philippine Islands.
- RESISTANT PLANTS. — 707. The Resistance of Plants to Diseases and Pests, in Relation to the Acidity of the Sap.

MEANS OF PREVENTION AND CONTROL. — 708. Patents for the Control of Diseases and Pests of Plants.

DISEASES OF VARIOUS CROPS. — 709. Principal Diseases of Vegetables, in Ontario, Canada. — 710. Lettuce Drop, Caused by *Sclerotinium Libertiana*, in Florida, U. S. A. — 711. Observations on the Parasitism of the Ascomycete, *Ustilina vulgaris*, in France.

#### IV. — WEEDS AND PARASITIC FLOWERING PLANTS.

712. The Worst Weeds in Cereal Crops, in Indiana, U. S. A. — 713. The Destruction of Weeds by Sodium Bisulphate.

#### V. — INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

GENERAL. — 714. Hymenoptera Parasitic on Injurious Insects, in Southern Brazil.

INSECTS, ETC., INJURIOUS TO VARIOUS CROPS. — 715. *Dictyothrips aegypticus*, a Thysanopteron Injurious to the "Black Morocco" Variety of Vine, in Cyrenaica. — 716. *Lonchaea aristella*, a Dipteron Injurious to the Fig Tree and the Wild Fig Tree in Italy. — 717. *Corythuca spinulosa* Gibson, a New Lace-bug on Wild Cherry, in New Jersey. — 718. Insects Injurious to Forest Trees in Sweden, in 1916.

*In quoting articles, please mention this REVIEW.*

## CONTENTS

### ABSTRACTS.

### AGRICULTURAL INTELLIGENCE.

#### I. — GENERAL INFORMATION.

- RURAL HYGIENE. — 719. The Chemical Nature of the Vitamines. Isomerism in Natural Antineuritic Substances. — 720. Experimental Studies on the Food Value of Bran, in France. — 721. Determination of the Indigestible Residue *in vitro* by the Action of Pancreatin on Wheat or its Milling or Baking Products. — 722. *Phymata noualhierii*, a Hemipterous Enemy of *Musca domestica* in Mexico.
- AGRICULTURAL EDUCATION. — 723. A First Year Course in Home Economics for Southern Agricultural Schools in the United States.
- EXPERIMENTAL AND ANALYTICAL WORK. — 724. Experimental Projects of the Division of Pomology of the University of California.

#### II. — CROPS AND CULTIVATION.

##### a) GENERAL.

- AGRICULTURAL METEOROLOGY. — 725. Agricultural Meteorology in New Castile, Spain — 726. Orchard Heating Against Frost in Utah, U. S. A.
- SOIL PHYSICS, CHEMISTRY AND MICROBIOLOGY. — 727. Soil Acidity and the Hydrolitic Ratio in Soils. — 728. Salts Injurious to Vegetation and their Relationship to the Irrigation of Arid and Semi-arid Regions. — 729. The Effect of Certain Factors on the Carbon Dioxide Content of Soil Air. — 730. The Relation of Weed Growth to Nitric Nitrogen Accumulation in the Soil. — 731. Protozoa and the Phenomena of Reduction in Soil. — 732. The Influence of Nitrifying Bacteria on Phosphates. — 733. Changes in the Nitrogen Content of Stored Soils.
- PERMANENT IMPROVEMENTS, DRAINAGE AND IRRIGATION. — 734. Report on Irrigation Surveys and Inspections in Canada for 1916-17. — 735. The Colorado River and its Utilisation. — 736. Schemes for Barrage-Reservoirs in Tunis. — 737. Irrigated Farms in Utah, U. S. A.
- TILLAGE AND METHODS OF CULTIVATION. — 738. Cultural Methods in Apple Orchards in Indiana, U. S. A.
- MANURES AND MANURING. — 739. The Decomposition of Green and Stable Manures in Soil. — 740. Sulphuric Acid and Fertiliser Industries in the United Kingdom. — 741. Some Availability Studies with Ammonium Phosphate and its Chemical and Biological Effects upon the Soil.

##### b) SPECIAL.

- AGRICULTURAL BOTANY, CHEMISTRY AND PHYSIOLOGY OF PLANTS. — 742. The Identification of Grasses by their Vegetative Characters. — 743. Composition of Citrus Leaves at Various Stages of Mottling. — 744 The Fats and Fatty Acids of the Grain Sorghums. — 745. The
- INTERNAT. INST. OF AGRIC. *Internat. Review of Science and Practice of Agriculture*, Year IX, No. VII. Rome, July, 1918.

- Chymase of *Solanum eleagnifolium*. — 746. New Observations on the Degradation of Inulin and "Inulids" in Chicory Roots. — 747. The Relation of Amide Nitrogen to the Nitrogen Metabolism of the Pea Plant. — 748. The Effect of One Plant on Another.
- PLANT BREEDING. — 749. Selection of Wheat in Ontario, Canada. — 750. Increased Self-Fertilisation of Petkuser Rye by Pure Line Selection, in the Netherlands. — 751. Selection Experiments with Two Cultivated Oats According to the Position of the Seed in the Spikelet, in France. — 752. The Inheritance of Characters of Rice, in India. — 753. Improving Alfalfa by Selection and Hybridisation in Manitoba, Canada.
- AGRICULTURAL SEEDS. — 754. Sugar Beet Seed Production and Stock in the United States.
- CEREAL AND PULSE CROPS. — 755. The Best Varieties of Italian Rice. — 756. "Early Della-rolle" Rice. — 757. Cultivation of Edible Leguminosae in Tunis for the Production of Dry Seeds.
- STARCH CROPS. — 758. *Canna edulis* in Trinidad.
- FORAGE CROPS, MEADOWS AND PASTURES. — 759. *Canavalia ensiformis* and *C. gladiata* in Trinidad and Tobago. — 760. Growing Sorghum in Kansas. — 761. Experiments on the Cultivation of *Paspalum dilatatum* in the Colonial Garden of Palermo.
- PLANTS YIELDING OILS, DYES AND TANNINS. — 762. Oil Yielding Plants of Indo-China.
- STIMULANT, AROMATIC, NARCOTIC AND MEDICINAL PLANTS. — 763. Coffee in Abyssinia. — 764. Tobacco in Honduras.
- VARIOUS PLANTS. — 765. Marvel of Peru (*Mirabilis Jalapa*), a Plant which should be Utilised. — 766. "Chamiso" (*Atriplex canescens*) and "Quelite Salado" (*Atriplex acanthocarpa*), Plants of the Arid Districts of North Mexico Suitable for growing in Saline Desert Soils.
- FRUIT GROWING. — 767. The "Miaray" (*Citrus miaray* n. sp.), a New Citrus Fruit of the Philippines. — 768. Soil Management Investigations in a Young Apple Orchard. — 769. Experimental Projects of the Division of Pomology of the University of California.
- VINE GROWING. — 770. The Present Position of Hybrid Bearers.
- FORESTRY. — 771. The Larches. — 772. Forest Trees of the Argentine. — 773. Swiss Forestry from 1914 to 1917.

### III. — LIVE STOCK AND BREEDING.

#### a) GENERAL.

- HYGIENE. — 774. Studies on Toxicity to Insects of Various Organic Compounds. — 775. Observations on the Immunity to Rinderpest of the Nellore (Indian) Cattle and of the Nellore-Native Grade Crosses, in the Philippines. — 776. Official Measures Adopted in the Argentine for the Control of the Tick Transmitting "Tristeza". — 777. Pathogenic Action of Ixodids. — 778. Thyroid Hyperplasia and the Relation of Iodine to the Hairless Pig Malady. — 779. Poultry Parasites. — 780. Infections Caused by *Bacterium pullorum* in Adult Fowls.
- ANATOMY AND PHYSIOLOGY: GENERALITIES. — 781. Studies in Calcium and Magnesium Metabolism.
- FEEDS AND FEEDING. — 782. The Nutritive Properties of Maize. — 783. Sudan Grass Silage — 784. Nutrition Investigations upon Cottonseed Meal and Cottonseed Flour. — 785. Food Value of the Pea Nut (*Arachis hypogaea*).

#### b) SPECIAL.

- HORSES. — 786. Potato Peelings and Heather as Coarse Fodder for Horses; Researches in Holland.
- CATTLE. — 787. A Study of the Rate and Economy of Gains of Fattening Steers. — 788. Influence of the Age of the Cow on the Composition and Properties of Milk and Milk Fat.

— 789. Researches on a New Galactagogue, in Italy. — 790. Breeds of Dairy Cattle in the United States. — 791. Establishment and Management of the Dairy Farm in India. — 792. Testing of Purebred Dairy Cows in New Zealand. — 793. Development of Cow Testing Associations in the United States.

PIGS — 795. Breeds of Pigs in Brazil.

POULTRY. — 796. A Study of the Effect of Cottonseed Meal versus Beef Scrap Upon the Egg Production, Fertility and Vitality of Poultry. — 797. Capons and Caponizing.

SERICULTURE. — The Second Rearing of Silkworms in Italy, during Summer and Autumn, 1917. — 799. Sericulture in Cyprus.

FISH CULTURE — 800. The Problem of the Restocking of the Alpine Lakes

#### IV. — FARM ENGINEERING

AGRICULTURAL MACHINERY AND IMPLEMENTS — 801. State Motorculture in France and Italy — 802. Agricultural Tractors in the United States, in 1918. — 803. Traction on Bad Roads or Land — 804. The Ford Tractor and the Oliver M O M. Plough in England. — 805. Disc-Harrow Trials at Montpellier. — 806 A Weeding Rake for Low Vines. — 807. Economic Advantages Resulting from the Use of Machinery in Harvesting Wheat — 808. A Hemp Harvester. — 809. Review of Patents.

FARM BUILDINGS. — 810. Movable Pig Houses.

#### V. — RURAL ECONOMICS.

811. — Important Factors in the Operation of Irrigated Farms in Utah, U. S. A — 812. Cost of Harvesting Wheat by Different Methods in the United States — 813. A Farm Accounting and Statistics Bureau of British Columbia, Canada.

#### VI. — AGRICULTURAL INDUSTRIES.

INDUSTRIES DEPENDING ON PLANT PRODUCTS. — 814. The Cream of Tartar in Plastered Wines, — 815. The Balance of Some Constituents of the Sugar Beet During the Manufacture of Sugar. — 816. Estimation of the Water Content of Products of the Sugar Industry by the Distillation Method. — 817. Bacterial Deterioration of Bread in Rome — 818. The Agen Plums and Prunes.

INDUSTRIES DEPENDING ON ANIMAL PRODUCTS. — 819. The Pasteurization of Sour, Farm-skimmed Cream for Buttermaking. — 820. A Substitute for Rennet Extracted from the Berries of *Solanum elaeagnifolium*.

#### PLANT DISEASES.

#### III. — DISEASES DUE TO FUNGI, BACTERIA AND OTHER

##### LOWER PLANTS.

GENERAL. — 821. Sooty Moulds of Southern France.

MEANS OF PREVENTION AND CONTROL. — 822. Simple Solutions of Copper Sulphate Against Vine Mildew. — 823. Patents for the Control of Diseases and Pests of Plants.

DISEASES OF VARIOUS CROPS. — 824. Diseases and Pests of Sorghum in Kansas, U. S. A. — 825. Diseases of Parsnips in England. — 826. The Control of a Disease of the Japanese Medlar caused by *Fusicladium pirinum* var. *Eriobotryae* — 827. Larch Canker (*Dasyscypha Willkommii*) in Sweden.

## V. — INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

MEANS OF PREVENTION AND CONTROL. — 828. The Value of the Coleopteron *Chilocorus bipustulatus* as a Destroyer of Scale Insects. — 829. The Toxicity to Insects of Various Organic Compounds.

INSECTS, ETC., INJURIOUS TO VARIOUS CROPS. — 830 *Dysdercus scassellatii*, n. sp., a Bug Observed on Cotton in Italian Somaliland. — 831. *Megastigmus bailestrerii*, a Hymenopteron Living on the Pistachio Tree and Turpentine Tree, in Sicily.

## EDITORIAL STAFF OF THE BUREAU OF AGRICULTURAL INTELLIGENCE AND PLANT DISEASES.

## CONTENTS

### FIRST PART: ORIGINAL ARTICLES.

- A. TARCHETTI. Mechanical Ploughing — Handling the Machines . . . . Page 905

### SECOND PART: ABSTRACTS.

## AGRICULTURAL INTELLIGENCE.

### I. — GENERAL INFORMATION.

- DEVELOPMENT OF AGRICULTURE IN VARIOUS COUNTRIES. — 832. The Agricultural Development of the East Coast of Sumatra.  
RURAL HYGIENE — 833. The Influence of Specific Carbohydrates and Grains, Other than Oats, on the Development of Scurvy. — 834. An Experimental Chronic Beriberic Syndrome. — 835. The Value of the Yeast Vitamine Fraction as Supplement to a Rice Diet — 836. Studies on the Digestibility of Some Nut Oils. — 837. Experiments on the Digestibility of Fish.

### II. — CROPS AND CULTIVATION.

#### a) GENERAL.

- SOIL PHYSICS, CHEMISTRY AND MICROBIOLOGY. — 838. Movement and Distribution of Moisture in the Soil. — 839. Studies in Soil Reaction as Indicated by the Hydrogen Electrode. — 840. Humus in Mulched Basins, Relation of Humus Content to Orange Production, and Effect of Mulches on Orange Production. — 841. Formation of Black Alkali (Sodium Carbonate) in Calcareous Soils. — 842. Influence of Carbonates of Magnesium and Calcium on Bacteria of Certain Wisconsin Soils. — 843. The Gases of Swamp Rice Soils: — Part III. A Hydrogen-Oxidising Bacterium from these Soils — Part IV. The Source of the Gaseous Soil Nitrogen.  
PERMANENT IMPROVEMENTS: DRAINAGE AND IRRIGATION. — 844. Artificial Glaciers for the Irrigation of Mountain Pastures, in India. — 845. Leakages from Irrigation Canals and Reservoirs in the U. S. A.  
MANURES AND MANURING. — 846. New Deposits of Guano in the Philippines. — 847. Fertilising Value of Ammonium Nitrate. — 848. The Potassium Problem and the Utilisation of Olive Oil Residue in Italy.

#### b) SPECIAL.

- AGRICULTURAL BOTANY, CHEMISTRY AND PHYSIOLOGY OF PLANTS. — 849. Plant Succession in the South African Thorn Veld. — 850. The Glandular Pubescence of Several Species of *Medicago*: Observations made in California, U. S. A. — 851. Behaviour of Sweet Potatoes in the Ground. — 852. Comparison of the Hourly Evaporation Rate of Atmospheres and Free Water Surfaces with the Transpiration Rate of *Medicago sativa*. — 853. The Influence of Certain Organic Substances on Plant Growth.

- INTERNAT. INST. OF AGRIC. *Internat. Review of Science and Practice of Agriculture*, Year IX, No. VIII, Rome, August, 1918.

- PLANT BREEDING.—854. Plant Breeding in India.—855. Selection of Native Oats and Barley in Denmark.—856. Pure-line Selection of Oats and Barley in Quebec, Canada.—857. Experiments on the Hybridisation of Maize in the Philippines.—858. Lint Percentage and Lint Index as Important Factors in the Selection of Cotton Varieties.—859. Investigations into the Colour of the Fruit in Hybrids of Tomato, Aubergine and Pepper, in the United States.
- CEREAL AND PULSE CROPS.—860. The Cultivation of Cercals in Spain.—861. Yields of Spring Grains in Illinois.—862. Researches on the Gases of Swamp Rice Soils, in India.—863. The Recurving of Milo and Some Factors Influencing it.
- STARCH CROPS.—864. Important Root Crops of the Philippines.
- FIBRE CROPS.—865. Cotton in Algeria in 1917.—866. Lint Percentage and Lint Index of Cotton and Method of Determination, Investigations in the United States.—867. The Cultivation of Gombo as a Textile Plant; Experiments in Mexico.
- SUGAR CROPS.—868. Results of Growing Sweet Sorghum in Piedmont, Italy.
- VARIOUS CROPS.—869. Plants Suitable for Paper-making in South Africa.
- FRUIT GROWING.—870. Investigations into the Autumn Growth of Fruit, in Italy.—871. The Common Honey Bee as an Agent in Plum Pollination.—872. The Mulching of Orange Groves in California and its Effect.
- VINE GROWING.—873. The Chasselas X Berlandieri 41 B Vine in Sicily.—874. The Influence of the Stock and Other Factors on the Quality of the Wine; Experiments Carried out in Sicily.

### III. — LIVE STOCK AND BREEDING.

#### a) GENERAL.

- HYGIENE.—875. Observations on Abortion Disease, in the United States.—876. Contribution to the Study of the Mortality of Calves: Coli-bacillary Broncho-pneumonia.—877. Method for Freeing Pigs from Lice.—878. On the Hereditary Transmission of Rabies.—879. Studies on Sarcoma in Chickens.—880. *Mallophaga* Ectoparasitic on Birds, in Formosa.
- FEEDS AND FEEDING.—881. A Study of the Dietary Essential, Water-Soluble B, in Relation to its Solubility and Stability towards Reagents.—882. A Comparative Study of the Behaviour of Purified Proteins towards Proteolytic Enzymes.—883. Study of the Proteins of Certain Insects with Reference to their Value as Food for Poultry.—884. Utilization of Farm Wastes for Feeding Live Stock, in U. S. A.
- BREEDING.—885. Observations on the Inheritance of Colour and Distribution of Sex in Certain Animals at the Government Cattle Farm, Hissar, Punjab, India.

#### b) GENERAL.

- HORSES.—886. Oatless Rations for Draught Horses.
- CATTLE.—887. Winter Steer Feeding Experiments in Indiana, U. S. A.—888. The Relation of the Quality of Proteins to Milk Production.
- SHEEP AND GOATS.—889. A Cross Between a Goat and a Ram, in Brazil.
- VARIOUS ANIMALS.—890. Study on the Land and Fresh-water Snails of Indo-China.

### IV. — FARM ENGINEERING.

- AGRICULTURAL MACHINERY AND IMPLEMENTS.—891. Electricity in Agriculture: Consumption, Distribution and Ploughing.—892. The Transformation of Motorcars and Motorlorries into Agricultural Tractors and Windlasses (Landrin System).—893. A Study of the Plough Bottom and its Action upon the Furrow Slice.—894. The Russell Turnip

Thinner. — 895. The "Universal" Electric-drive Thresher. — 896. Safety Devices for Chaff-cutters. — 897. Balance for the Direct Reading of the Lint Percentage of Cotton. — 898. The Gibaudan Alcohol-meter. — 899. Review of Patents.  
 FARM BUILDINGS. — 900. Rapid House Construction with Concrete Studs

## V. — RURAL ECONOMICS.

901. Study of some Egyptian Farms. — 902. Studies in the Cost of Market Milk Production in the United States.

## VI. — AGRICULTURAL INDUSTRIES.

INDUSTRIES DEPENDING ON PLANT PRODUCTS. — 903. The Intrinsic Values of Grain, Cottonseed, Flour and Similar Products, Based on the Dry-Matter Content. — 904. The Utilisation of Sisal Waste, for the Production of Alcohol. — 905. The Beet Sugar Industry in the Netherlands. — 906. The Fat of the Residue of the Decortication of Rice. — 907. South African Paper-making Plants.  
 INDUSTRIES DEPENDING ON ANIMAL PRODUCTS. — 908. A Substitute for Litmus for Use in Milk Cultures. — 909. Preliminary Note on Certain Changes in Some of the Nitrogenous Constituents of Milk Caused by Bacteria. — 910. Experiments on Determination of Cow Manure in Milk; Moisture Content and Solubility of Cow Manure. — 911. Methods Adopted in the Production of "Clotted Cream" in Devonshire and Cornwall, England. — 912. Studies in Butter Shrinkage. — 913. The Relation of *Oidium lactis* and *Penicillium* to the Keeping Qualities of Butter. — 914. Varieties of Cheese: Descriptions and Analyses. — 915. Study on the Normal Production of Gas in Cheese: Investigations at the Agricultural Experiment Station of Hoorn, Netherlands. — 916. The Growth of Green Mould (*Penicillium glaucum*) for the Manufacture of Blue Cheeses. — 917. Researches on the Physical and Chemical Constants of the Oily Matter of the Egg ("Eieröl").  
 AGRICULTURAL PRODUCTS: PRESERVING, PACKING, TRANSPORT, TRADE. — 918. The Relative Influence of Microorganisms and Plant Enzymes on the Fermentation of Maize Silage. — 919. Changes in the Composition of Sweet Potatoes left in the Ground when Mature. — 920. The Influence of Salt on the Changes Taking Place in Storage Butter.

## PLANT DISEASES.

### II. — DISEASES NOT DUE TO PARASITES OR OF UNKNOWN ORIGIN,

921. "Fucha" of the Cotton Plant, in the Department of Boyacá, Republic of Colombia. — 922. The Mottling of Citrus Leaves in Relation to their Composition. — 923. "Møisted Grenader", a Norwegian Variety of Oat Resistant to Lodging. — 924. "Chasselas" and "Berlandieri 41 B" Vines Resistant to Bramble-leaf Disease.

### III. — DISEASES DUE TO FUNGI, BACTERIA AND OTHER LOWER PLANTS.

GENERAL. — 925. Bacteria and Fungi Recorded as Parasitic on Cultivated Plants in the Province of Turin and Adjacent Regions in 1916. — 926. Uredinales of the Andes, South America. — 927. *Nesara viridula* and the Kernel Spot of Pecan.  
 RESISTANT PLANTS. — 928. Selected Indian Wheats Resistant to Rust and Lodging.

MEANS OF PREVENTION AND CONTROL. — 929. Patents for the Control of Diseases and Pests of Plants.

DISEASES OF VARIOUS CROPS. — 930. Diseases and Pests of the Sweet Potato in the Philippines. — 931. Experiments on the Action of Polysulphide Against Oidium of the Vine.

#### IV — WEEDS AND PARASITIC FLOWERING PLANTS.

932. Mexican Marigold (*Tagetes minuta*), a Weed in Rhodesia.

#### V. — INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

GENERAL. — 933. *Aleyrodidae* Injurious to Various Plants in Different Countries.

MEANS OF PREVENTION AND CONTROL. — 934. West Indian and North American Chalcids.

— 935. *Ipobracon saccharalis* n. sp. and *Microdus diatraeae*, Hymenoptera Parasitic on *Diatraea saccharalis*, a Microlepidopteron Injurious to Sugar Cane, in British Guiana.

INSECTS, ETC., INJURIOUS TO VARIOUS CROPS. — 936. Weevils which Affect the Potato, Sweet Potato and Yam. — 937. *Physothrips marshalli* n. sp., a Thrips Observed on Potato and Other Plants in the Gold Coast. — 938. Damage Caused to the Cotton Plant in Algeria by the Microlepidopteron *Glechia gossypiella*. — 939. The Sugar-Cane Frog-hopper in Grenada, Lesser Antilles. — 940. Hemiptera Living on Cultivated Plants in the Belgian Congo. — 941. *Physothrips setiventris* n. sp., and *Phys. lefroyi*, Thrips Injurious to Tea in India. — 942. Pests Observed on Tobacco from Réunion Grown in Mauritius. — 943. *Agrolimax agrestis*, a Molluscan Garden Pest, in New York State. — 944. *Stephanitis rhododendri*, Injurious to Rhododendrons in France. — 945. Cecidomyid Flies Living on *Olea chrysophylla* and *O. europaea* in Eritrea and Italy Respectively. — 946. *Hoplia floridana* n. sp., a Coleopteron Injurious to Citrus, in Florida. — 947. *Nezara viridula*, a Hemipteron Injurious to Pecan Trees in Georgia, U. S. A. — 948. *Evetria buoliana*, a Microlepidopteron Injurious to Pines in France.

#### VI. — INJURIOUS VERTEBRATES.

949. The Control of Field Mice by Acetylene Gas

## CONTENTS

### FIRST PART: ORIGINAL ARTICLES.

A TARCHETTI. -Mechanical Ploughing. Methods of Ploughing without Ridges . Page 1017

### SECOND PART: ABSTRACTS.

## AGRICULTURAL INTELLIGENCE.

### I — GENERAL INFORMATION.

LEGISLATIVE AND ADMINISTRATIVE MEASURES — 950. Facilities accorded to Official Agronomists for the Purchase of Automobiles, in Canada.

RURAL HYGIENE. — 951. On the Possibility that Man can Live on a Diet Containing No Fat ; Researches in Denmark. — 952. The Feeding of Cattle and "Barlow's Disease" in Children Caused by Milk — 953 Bacterial Precipitins and the Detection of *Bact. botulinus* in Preserved Foods by the Thermo-Precipitation Method.

EXPERIMENTAL AND ANALYTICAL WORK. — 954. Investigations into the Possibility of Calculating the Experimental Error in Field Experiments. — 955. Agricultural Experiment Stations of Canada.

### II. — CROPS AND CULTIVATION.

#### a) GENERAL.

AGRICULTURAL METEOROLOGY. — 956. Chemical Composition, from an Agricultural Point of View, of Rainwater Collected at Montevideo, Uruguay, from 1909 to 1912.

SOIL PHYSICS, CHEMISTRY AND MICROBIOLOGY. — 957. Some Notes on the Direct Determination of the Hygroscopic Coefficient. — 958. The Relationship Between Absorption and Coagulation With Respect to the Mineral Colloids of the Soil. — 959. Influence of Nitrates on Nitrogen-Assimilating Bacteria.

MANURES AND MANURING. — 960. New Coprolite Works in the United Kingdom. — 961. Effect of Sulphur on Different Crops and Soils. — 962. An Estimate of the Amount of Fertilisers Required for Food Production in Norway.

#### b) SPECIAL.

AGRICULTURAL BOTANY, CHEMISTRY AND PHYSIOLOGY OF PLANTS. — 963. Plants Tolerating Salt. — 964. A Physical and Chemical Study of the Kafir Kernel in the United States. — 965. Two New Vegetable Globulins. — Stizolobin and the Globulin of Buckwheat. — 966. The High Calcium Content of Some Cucurbitaceous Vines. — 967. Inulin in the Sunflower-Jerusalem Artichoke Graft. — 968. Reactions of the Phosphorus of the Thickened Root of the Flat Turnip. — 969. Injurious Action of Magnesium Carbonate on Plants. — 970. Absorption of Nutrients as Affected by the Number of Roots Supplied with the Nu-

INTERNAT. INST. OF AGRIC. *Internat. Review of Science and Practice of Agriculture*. Year IX No. IX. Rome, September, 1918.

- trient. — 971. The Formation of Nitrites from Nitrates in Aqueous Solution by the Action of Sunlight, and the Assimilation of the Nitrites by Green Leaves in Sunlight.
- PLANT BREEDING. — 972. Choice of Material for Isolating Inflorescences in Selection Work. — 973. The Selection of Barley in Algeria. — 974. Selection of Rice in the Philippines. — 975. Apparent Mutations of Colour in the Beetroot Due to the Effect of Vicinity, in Sweden. — 976. A Further Note on the Genetics of *Fragaria*.
- CEREAL AND PULSE CROPS. — 977. Wheat, Yields per Acre and Prices, by States, for the 50 years 1866-1915, in the United States. — 978. Cultivation of Manitoba Wheat in Touraine, France.
- FORAGE CROPS, MEADOWS AND PASTURES. — 979. Red Clover and its Varieties, in New South Wales, Australia. — 980. *Enneapogon mollis* in Ascension Island. — 981. Experiments on Steppe Pasture in the Dehesa de Nuestra Señora del Pilar, the Central Steppe of Spain.
- FIBRE CROPS. — 982. The Time at which Cotton Uses the Most Moisture. — 983. Zagnipe. — 984. The Mulberry as a Textile-Fibre Plant.
- CROPS YIELDING OILS, DYES AND TANNINS. — 985. "Sélé", "Cocorico" and *Ximema americana*, African Oil-Yielding Plants. — 986. *Elaeis Poissonnii*, a New Species of Oil Palm, in the Cameroons. — 987. The Oil Content, Keeping Qualities and Commercial Possibilities of Para Rubber Seed.
- RUBBER, GUM AND RESIN PLANTS. — 988. The Effects of Tapping and Wintering on the Food Reserves of *Hevea*. — 989. Value of the Results Obtained by the Use of Apparatus for Estimating the Rubber in Latex. — 990. Bibliography of the Publications on Rubber which Have Appeared Between 1910 and 1916.
- SUGAR CROPS. — 991. Measurements of the Growth of Sugar Cane; Observations Made in the Dutch East Indies.
- STIMULANT, AROMATIC, NARCOTIC AND MEDICINAL PLANTS. — 992. Analysis of "Cocoa Tea" a New Substitute Used in Great Britain. — 993. Trials with Réunion Tobacco in Mauritius, in 1916-1917. — 994. Medicinal Plants of the Italian Colonies.
- FRUIT GROWING. — 995. Pine-Apple Growing in the Azores. — 996. Overhead Irrigation of Strawberries in Illinois, U. S. A.
- FORESTRY. — 997. The Douglas Fir, Its Importation and Cultivation in Central Europe. — 998. The Utilisation of the Dead Leaves of Forests.

### III. — LIVE STOCK AND BREEDING.

#### a) GENERAL.

- HYGIENE. — 999. Purifying Water for Stock. — 1000. Cut-throat Grass (*Panicum Combsii*) and Salt Sickness: Investigations in the United States. — 1001. Gossypol, a Toxic Substance in Cottonseed. — 1002. Observations on the Etiology of Epizootic Lymphangitis. — 1003. Preliminary Report on the Virulence of Certain Body Organs in Rinderpest. — 1004. Observations on the Control of *Rhipicephalus annulatus australis*, in Queensland, Australia. — 1005. Thymic Acid and Thymol in the Treatment and Prevention of Intestinal Coccidiosis in Cattle. — 1006. Life History of *Ascaris lumbricoides* and Related Forms. — 1007. "Askaron", a Toxic Constituent of Intestinal Worms, Especially of Ascarids, and its Biological Action. — 1008. I. Morphology of Normal Pigs' Blood. II. Effects of Muscular Exercise and the Heat of the Sun on the Blood and Body Temperature of Normal Pigs. — 1009. Investigations into the Action of the Thyroid Gland, in the United States.
- FEEDS AND FEEDING. — 1010. Influence of Time of Digestion on the Hydrolysis of Casein in the Presence of Starch. — 1011. The Influence of the Food on the Vitamine Content of the Milk. — 1012. Aquatic Plants Which May Be Used as a Food for Cattle; Investigations in Holland. — 1013. Digestible Hay Cake and Hay Paste.

#### b) SPECIAL.

- HORSES. — 1014. The Zebra and its Hybrids as Domestic Animals.
- CATTLE. — 1015. The Origin and Improvement of Cattle in Columbia.

GOATS. — 1016. The Angora Goat in Madagascar.

PIGS. — 1017. Mussels as Food for Pigs: Investigations in Denmark.

POULTRY — 1018. Experimental Modification of Germ Cells and the Effect of Daily Inhalation of Ethyl Alcohol and other Poisons on the Progeny of Poultry. — 1019. The Use of Weevily Wheat for Feeding Poultry. — 1020. The Use of Seaweed in Poultry Feeding.

#### IV. — FARM ENGINEERING.

AGRICULTURAL MACHINERY AND IMPLEMENTS. — 1021. Agricultural Machinery in the United Kingdom. — 1022. Hints on the Use of an Agricultural Tractor. — 1023. The Dirube and Sabaria System of Cable Traction Applied to Agriculture. — 1024. Trials of Disc-Harrows with Tractors, in France. — 1025. The Marti Earth-Grab. — 1026. Machines Used for Harvesting Cereals in the Argentine. — 1027. The Chiesa Drier with Multiple Recipients. — 1028. The Use of Potato-Drying Plant in Rhodesia. — 1029. New Applications of Artificial Cold. — 1030. Review of Patents

#### V. — RURAL ECONOMICS.

1031. Farm Management and Farm Profits on Irrigated Land in the Provo Area (Salt Lake Valley) U. S. A. — 1032. The Economic Results of the Overhead Irrigation of Strawberries in Illinois.

#### VI. — AGRICULTURAL INDUSTRIES.

INDUSTRIES DEPENDING ON PLANT PRODUCTS. — 1033. A New Method for Determining the Watering of Wine — 1034. The Influence of the Vegetable Function of Yeast on the Yield of Alcohol, a New Interpretation of Fermenting Power — 1035. Decortication of Wheat Previous to Milling — 1036. Oil of *Pistacia lentiscus*. — 1037. Experiments on the Biological Saponification of Various Fats from the French Colonies — 1038. The Utilisation of Paddy at the Present Day. — 1039. Drying Vegetables. — 1040. "Gelso-lino" (Mulberry Flax), in Italy. — 1041. The Manufacture of Paper Pulp from Dead Leaves — 1042. The Cotton Mill Industry of the World. — 1043. The Carbonisation and Distillation of Peat, Wood-shavings, Household Waste and other Light Organic Products

INDUSTRIES DEPENDING ON ANIMAL PRODUCTS. — 1044. The Four Essential Factors in the Production of Milk of Low Bacterial Content. — 1045. The Enzymes of Milk and Butter. — 1046. The Deterioration of Condensed Milk; Estimation of its Acidity. — 1047. Bacterial Precipitins and the Detection of *Bact. botulinus* in Preserved Foods by the Thermo-Precipitation Method.

#### PLANT DISEASES.

##### II. — DISEASES NOT DUE TO PARASITES OR OF UNKNOWN ORIGIN,

1048. Researches on Apple-Spot Diseases. — 1049. The Injurious Action of Magnesium Carbonate on Plants.

##### III. — DISEASES DUE TO FUNGI, BACTERIA AND OTHER LOWER PLANTS.

GENERAL. — 1050. The Morphology and Biology of *Blepharospora cambivora*, an Agent of the "Ink Disease" of the Chestnut.

RESISTANT PLANTS. — 1051. The Resistance of Manitoba Wheat to Fungous Diseases.

MEANS OF PREVENTION AND CONTROL. — 1052. Patents for the Control of Diseases and Pests of Plants.

DISEASES OF VARIOUS CROPS — 1053. Cereal Mildew (*Sclerospora macrospora*), Observed on Maize, in Piedmont, Italy. — 1054. Smuts Injurious to Sorghum in the Presidency of Bombay. — 1855. *Bacillus Solanacearum*, Injurious to *Ricinus*, in U. S. A. — 1056. The Danger of Burying Felled Coconut Trees Between Rows of Rubber Trees in the Federated Malay States. — 1057. Diseases of Sugar-Cane in Tropical and Subtropical America, especially the West Indies. — 1058. *Cercospora s. lanicola* and *Cercospora* sp., Fungi respectively injurious to Tobacco and Sesame in the State of Pernambuco, Brazil

## V. — INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

MEANS OF PREVENTION AND CONTROL. — 1059. *Aphelinus borellii* n. sp. and *Metataptis torquatus*, Hymenoptera Parasitic on Other Insects. — 1060. *Casca luzonica* n. sp., a Hymenopteron Endophagous on the Scale-Insect *Schizaspis lobata*, in the Philippines. — 1061. The Use of Bats in the Control of Insects, especially *Tortricidae*, Injurious to Pine Woods.

INSECTS, ETC., INJURIOUS TO VARIOUS CROPS. — 1062. The Alfalfa Looper (*Autographa cavi-jornica*), Injurious to Various Cultivated Plants in Canada. — 1063. The West Indian Mole Cricket (*Scapteriscus vicinus*), Injurious to Crops in Porto Rico. — 1064. *Trioza atacris*, a Hemipteron Injurious to Laurel in New Jersey, U. S. A. — 1065. *Papilio thoantiades*, a Macrolepidopteron Injurious to Citrus Plants and the Hymenopteron *Pteromalus caridei* its Natural Enemy, in the Argentine. — 1066. A Tortricid Moth Injurious to the Chestnut Tree, in Italy. — 1067. *Stutolobus trilineatus* n. sp., a Hemipteron (Homoptera) living on Cress in Louisiana, U. S. A.

## CONTENTS

### FIRST PART: ORIGINAL ARTICLES.

A. TARCHETTI. -Mechanical Ploughing. Methods of Ploughing without Ridges . Page 1129

### SECOND PART: ABSTRACTS.

## AGRICULTURAL INTELLIGENCE.

### I. — GENERAL INFORMATION.

DEVELOPMENT OF AGRICULTURE IN VARIOUS COUNTRIES. — 1068. The Organisation of Colonial Agriculture in Indo-China and France. — 1069 Agriculture in Cyprus.

RURAL HYGIENE. — 1070. On the Bactericidal Action of Sunlight (Total White Light or Coloured Light). — 1071. Researches, from the Standpoint of Food Hygiene, on the Ganglionic and Muscular Virulence of Macroscopically Healthy Organs in Generalised Bovine and Swine Tuberculosis. — 1072 Rice in the Chemistry of Food. — 1073 Coffee Substitutes Made with Lupins and their Disadvantages. — 1074. The Antiseptic Value of Some Essential Oils.

EXPERIMENTAL AND ANALYTICAL WORK. — 1075. Recent Investigations at the Imperial Institute.

AGRICULTURAL SHOWS AND CONGRESSES. — 1076 Australian Interstate Conference of Agricultural Scientists.

### II. — CROPS AND CULTIVATION.

#### a) GENERAL.

AGRICULTURAL METEOROLOGY. — 1077. Investigations into the General Movements of the Atmosphere. — 1078. The Effects of Weather on the Yields of Potatoes, Wheat and Maize, in Ohio, U. S. A.

SOIL PHYSICS, CHEMISTRY AND MICROBIOLOGY. — 1079. The Reserves of Soil Water During a Drought. — 1080. The Effect of Irrigation Water and Manure on the Nitrates and Total Soluble Salts of the Soil.

PERMANENT IMPROVEMENTS : DRAINAGE AND IRRIGATION. — 1081. Evaporation from the Surfaces of Water and River-Bed Materials. — 1082 Irrigation of Alfalfa in Imperial Valley, California. — 1083. Drainage Instruction and Demonstration in Canada.

TILLAGE AND METHODS OF CULTIVATION. — 1084. Dry Farm Crop Rotations and Cultural Methods in U. S. A. — 1085. Experiments on the Electro-culture of Growing Crops, in Scotland.

#### b) SPECIAL.

AGRICULTURAL BOTANY, CHEMISTRY AND PHYSIOLOGY OF PLANTS. — 1086. Seeds and Plants Introduced into the United States during the Period from January 1 to March 31, 1916. — 1087. Plant Ecology and its Relation to Agriculture. — 1088. Crop Centres of the United.

INTERNAT. INST. OF AGRIC. *Internat. Review of Science and Practice of Agriculture* Year IX No. X. Rome, October, 1918.

- States from an Ecological Point of View. — 1089. A Note on the Analysis and Composition of the Seed of the Silver Maple (*Acer Saccharinum*). — 1090. The Chemical Composition of the Loganberry (*Rubus Idaeus Loganii*). — 1091. The Chemical Composition of the Pineapple. — 1092. Stachydrin, a New Nitrogenous Compound Isolated from Alfalfa Hay in the United States. — 1093. Discovery of a Cyanogenetic Principle in Toadflax (*Linaria minor* Desf.). — 1094. Composition of a Plant Salt from the Cameroons. — 1095. Relation Between Pigmentation and Oxidation Phenomena in Plants; a Study of the Comparative Respiration of Red Leaves and Green Leaves. — 1096. Immunity of Plants to the Principles Formed by them. — 1097. Antagonism Between Growth and Reproduction in Plants; Factors Influencing these two Processes.
- PLANT BREEDING.** — 1098. The Heredity of Early and Late Ripening in an Oat Cross, in England. — 1099. Selection of Maize Resistant to Smut (*Ustilago Zeae* Beck), in the United States. — 1100. Observations on some Degenerate Strains of Potatoes. — 1101. Deli Tobacco with Petiolate Leaves Probably Resulting from Mutation of a Single Factor, at Sumatra.
- AGRICULTURAL SEEDS.** — 1102. Variations in Seed Tests Resulting from Errors in Sampling.
- CEREAL AND PULSE CROPS.** — 1103. Date and Rate-of-Seeding Tests with Spring Grains under Irrigation. — 1104. Comparative Cultural Experiments with Several Varieties of Oats in South and Central Sweden. — 1105. The "Kyko" Oat (*Avena sativa* var. *obtusata*) from Cyprus. — 1106. The Control of Weeds in Ricefields by Rolling. — 1107 "Hue-ky" Rice, an Indo-Chinese Variety of Good Quality, especially suited for Western Cochin-China.
- FIBRE CROPS.** — 1108. The Production, Preparation and Uses of Raffia. — 1109. Tests with Varieties of Cotton in Cyprus. — 1110. Sunflower Pith, the Wood and Bark of the Baobab for use in Paper Making.
- CROPS YIELDING OILS, DYES AND TANNINS.** — 1111. Olive Growing in Australia. — 1112. Oil-Yielding Seeds of British India. — 1113. Oil-yielding Plants of South and West Africa. — 1114 The Extraction of Berberine from "Michai" (*Berberis Darwinii*) and "Calafate" (*B. Bux folia*), in the Argentine. — 1115. The Cake from *Strephonema* sp. as Tanning Material.
- RUBBER, GUM AND RESIN PLANTS.** — 1116. Experiments with Hevea in the Dutch East-Indies. — 1117. Investigations into Different Methods of Tapping and their Influence on the Yield of the Rubber Plants, in Sumatra.
- STIMULANT, AROMATIC, NARCOTIC AND MEDICINAL PLANTS.** — 1118. Essential Oils from Cyprus. — 1119. Plants Suitable for the Extraction of Thymol. — 1120. Tobacco Growing in Cyprus. — 1121. *Hyoscyamus muticus*, the "Mountain Hemp" of Egypt, the Sudan and India, as a Source of Atropine. — 1122. Squills (*Urginea Scilla*) and Liquorice (*Glycyrrhiza glabra*) in Cyprus.
- VARIOUS CROPS.** — 1123. *Leucaena glauca*.
- HORTICULTURE.** — 1124. Chemical Composition of the Loganberry (*Rubus Idaeus Loganii*). — 1125. A Contribution to the Study of the Chemical Composition of Pineapple and the Materials Necessary to its Cultivation.

### III. — LIVE STOCK AND BREEDING.

#### a) GENERAL.

- HYGIENE.** — 1126. Immunity Studies on Anthrax Serum. Transformation of Pseudoglobulin into Globulin. — 1127. On the Possibility of the *Post Mortem* Generalisation of the Virus of Rabies. — 1128. Efficacy of Some Anthelmintics. — 1129. Ticks Found on Domestic Animals in New Zealand. — 1130. On a Mite of the Genus *Tyroglyphus*, an Accidental Parasite of the Horse. — 1131. Experiments on the Treatment of "Tristeza" in the Argentine. — 1132. Two New Flukes from the Dog.
- FEEDS AND FEEDING.** — 1133. Albuminoids in the Feeding of Live Stock. — 1134. The Treatment of Lupinus in Order to Eliminate their Toxic Properties; Researches in Holland. —

1135. Vine Fodder: The Value and Utilisation of Vine Leaves. — 1136. Tree Leaves in Live Stock Feeding. — 1137. Investigations into the Composition of Seaweeds with a View to their Utilisation as Cattle Food, in the Netherlands. — 1138. Various Cakes from Cyprus and Africa; Straw and Hay from Cyprus; Composition and Food Value. — 1139. Sunflower Pith as a Cattle Food.

SHEEP AND GOATS. — 1140. Cross Between Sheep and He-Goat and Between Goat and Ram, in Brazil.

FIGS. — 1141. The Utilisation of the Stomach Contents of Slaughtered Cattle for Feeding Pigs.

FISH CULTURE. — 1142. Researches on the Specific Distinction Between the River Trout, Lake Trout and Sea Trout and the Acclimatisation of Fresh Water Trout to Salt Water. — 1143. The Death of Carp Suffering from Cyclochaetosis, Observed in Italy.

#### IV. — FARM ENGINEERING.

AGRICULTURAL MACHINERY AND IMPLEMENTS. — 1144. Motorculture by Electricity. — 1145. Public Mechanical Cultivation Trials Organised by the French Ministry of Agriculture of Noisy-le-Grand, France, in Spring, 1918. — 1146. The Production of Agricultural Material and the Maximum Price for Agricultural Machinery and Implements, in France. — 1147. Exports of Implements, Twine, Tractors and Gas Engines from the U. S. A., for the Period 1915 to 1917. — 1148. The Price of Binder Twine in the U. S. A., in 1918. — 1149. The JEAN BACHE Vineyard Tractor. — 1150. Rotary Harrow Attachment for Sulky and Multiple Gang Ploughs. — 1151. The Production of Groats and Oatmeal. — 1152. The SCOTT Process and Plant for Drying Potatoes. — 1153. Peanut Decorticators. — 1154. Machines for the Recovery of Grape Stones for the Production of Oil. — 1155. Review of Patents.

#### V. — RURAL ECONOMICS.

1156. — Influence of a City on Farming.

#### VI. — AGRICULTURAL INDUSTRIES.

INDUSTRIES DEPENDING ON PLANT PRODUCTS — 1157. Research on Malting and a New Process for the Reduction of Malting Loss. — 1158. The Capacity of Wheat and Mill Products for Moisture. — 1159. The Production of Groats and Oatmeal. — 1160. The Decortication of Peanuts. — 1161. Vinegar from Waste Fruits. — 1162. The Scott Process and Plant for Drying Potatoes. — 1163. Straw Hats and Braids in South America.

INDUSTRIES DEPENDING ON ANIMAL PRODUCTS. — 1164. The Condensed Milk Industry in Japan. — 1165. The Reducing Ferments of Milk. — 1166. The Churning of Sweet Cream and Acid Cream: Investigations in Sweden. — 1167. The Preparation of Home-made Rennet. — 1168. The Preservation of Meat: Researches on the Presence of Living Elements in Normal Muscular Tissue (Parasitism and Microbiosis). — 1169. Food Preparations Made with Blood and Meat Mixed with Yeast.

AGRICULTURAL PRODUCTS: PRESERVING, PACKING, TRANSPORT, TRADE — 1170. The Preservation and Efficient Ripening of Silage in Warm Countries: the Use of Hydrochloric Acid or other Acid Mineral Substances and Special Substances.

#### PLANT DISEASES.

##### II. — DISEASES NOT DUE TO PARASITES OR OF UNKNOWN ORIGIN,

LEGISLATIVE AND ADMINISTRATIVE MEASURES FOR THE PROTECTION OF CROPS. — 1171. An Order of the Government of the Colony of Trinidad and Tobago Placing the Coconut Butterfly (*Brassolis sophorae*) Among the Plant Pest.

### III. — DISEASES DUE TO FUNGI, BACTERIA AND OTHER LOWER PLANTS.

GENERAL. — 1172. Myxomycetes and Fungi of the Province of Verona, Italy. — 1173. Fungi from Singapore, Malacca and Campania (Italy).

RESISTANT PLANTS. — 1174. Maize Resistant to *Ustilago Zeae* in the U. S. A.

MEANS OF PREVENTION AND CONTROL. — 1175. Patents for the Control of Diseases and Pests of Plants.

DISEASES OF VARIOUS CROPS. — 1176. *Odontia Sacchari* n. sp. and *O. saccharicola* n. sp., Basidiomycetes Living on Sugar Cane, in Porto Rico, Antilles. — 1177. *Phyllosticta Rabeti*, a Denteromycete, the Specific Agent of "Rabbia" or Anthracosis of the Chick Pea, in Italy.

### IV. — WEEDS AND PARASITIC FLOWERING PLANTS.

1178. — The Control of *Imperata arundinacea* (Gramineae) by means of *Leucaena glauca* (Leguminosae) in the Philippines. — 1179. The Control of Weeds in Ricefields.

### V. — INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

GENERAL. — 1180. Notes on Some Aphides Collected in South Eastern Russia.

MEANS OF PREVENTION AND CONTROL. — 1181. Acclimatisation Experiments in Italy with the African Hymenopteron *Opius concolor*, a Parasite of the "Olive Fly".

INSECTS, ETC., INJURIOUS TO VARIOUS CROPS — 1182. *Pachymerus quadrimaculatus*, a Weevil Injurious to the Black-Eye Pea (*Vigna catjang*) in Trinidad. — 1183. *Phthorimaea operculella*, a Microlepidopteron Injurious to Potatoes, New for Indiana, U. S. — 1184 *Oxycaenus hyalinipennis*, a Hemipteron Injurious to Cotton, in Italian Somaliland. — 1185. *Nysius ericae*, the False Chinch Bug, Injurious to Sugar Beets and Cruciferous Garden Crops in the United States. — 1186. *Aleurocanthus woglumi*, a Hemipteron Injurious to Various Cultivated Plants, in Cuba.

### VI. — INJURIOUS VERTEBRATES.

1187. *Bacterium murisepticum*, the Specific Agent of an Infections Disease of Field Mice (*Pitymys savii*), in Apulia, Italy.

## CONTENTS

### SECOND PART: ABSTRACTS.

### AGRICULTURAL INTELLIGENCE.

#### I. — GENERAL INFORMATION.

- LEGISLATIVE AND ADMINISTRATIVE MEASURES. — 1188. Encouragement in the Growing of the Castor Oil Plant in Indo-China — 1189. Measures taken by the Administration in Indo-China to Promote the Development of Sericulture.
- DEVELOPMENT OF AGRICULTURE IN VARIOUS COUNTRIES. — 1190. Native Agriculture in Cochin-China. — 1191. Foods of Tonkin.
- RURAL HYGIENE. — 1192. Contribution to the Study of the Culicidae of French Guiana. — 1193. The Tatu (*Tatusia novemcincta*), Host of *Schizotrypanum cruzi*, the Agent of "Minas Meningitis", in Brazil. — 1194. I) Vitamines and Symbionts. — II). The Action of Symbionts on the Constituents of Fats — 1195. Studies on Nitrogen Poisoning. — 1196. The Comparative Influence of Carbohydrates and Fats on the Utilisation of Food Proteins. — 1197. On the Minimum of Sugar in the Diet and Hitherto Unconsidered Sources of Carbohydrates. — 1198. The Food Value of the Banana.
- AGRICULTURAL EDUCATION. — 1199. Foundation of a High School of Agriculture and Forestry in Indo-China; Prospectus of Subjects Taught.

#### II. — CROPS AND CULTIVATION.

##### a) GENERAL.

- AGRICULTURAL METEOROLOGY. — 1200. Partial Correlation Applied to Dakota Data on Weather and Wheat Yield — 1201. A Method Recommended in the Argentine for Avoiding Frost Damage to Cane Stools — 1202. Relation of the Density of Cell Sap to Winter Hardiness in Small Grains.
- SOIL PHYSICS, CHEMISTRY AND MICROBIOLOGY. — 1203. Investigations into Flocculating Power in Soil. — 1204. The Action of Neutral Salts on Humus and Other Experiments on Soil Acidity. — 1205. Isolation of Cyanuric Acid from Soil, in the United States. — 1206. New Observations on the Biological Absorption of Methane and the Distribution of KAEBERER and SÖNINGEN Methane Organisms in Soils, Mud and Farm Manures.
- MANURES AND MANURING; ANTICRYPTOGAMIC PRODUCTS. — 1207. Experiments on the Influence on the Fertilising Power of Sewage of the Bacteria it Brings to the Soil. — 1208. Experiments on the Action of Manganese Dioxide on Nitrogenous Organic Substances, Especially Amides, With a View to the Use of this Dioxide as a Fertiliser. — 1209. Analysis of Phosphatic Fertilisers. — 1210. The Production and Consumption of Copper Sulphate and Copper Products in Italy.

##### b) SPECIAL

- AGRICULTURAL BOTANY, CHEMISTRY AND PHYSIOLOGY OF PLANTS. — 1211. The Relationship between the Constituents of the Ashes of Plants Diversely Fertilised. — 1212. Relation between the Total Phosphoric Acid and that of the Lecithins in Different Varieties of Peas. — 1213. "Sarrothamnine" and "Genisteine", New Alkaloids from the Scotch Broom. — 1214. Hydrocyanic Acid Content of the "Pe-gya" Burma Bean (*Phaseolus lunatus* var.) and its Estimation. — 1215. Studies on the Evolution of the Sweet Princi
- INTERNAT. INST. OF AGRIC. *Internat. Review of Science and Practice of Agriculture* Year IX No. 11. Rome, November, 1918.

- ples of Sorghum: Sugar Content at the Various Stages of Growth and the Influence of Castration. — 1216. The Effect of Tobacco Smoke and of Methyl Iodide Vapour on the Growth of Certain Microorganisms. — 1217. Relation of the Density of Cell Sap to Winter Hardness in Small Grains; Investigations in the U. S. A. — 1218. The Action of Ultra-Violet Rays on Sugar Cane, Pineapple and Banana, in Hawaii. — 1219. Physical Factors of Tropism. — 1220. Artificial Budding of Roots. — 1221. The Influence of Pollinisation and other External Factors on the Floral Organs and the Flowering Period; Research in Japan. — 1222. Experiments on "Pneumatocarps".
- PLANT BREEDING. — 1223. Inheritance of the Characters of the Endosperm in Hybrids between Hard and Soft Wheats in the United States. — 1224. On a Case of Permanent Variation in the Glume Lengths of Extracted Parental Types and the Inheritance of Purple Colour in the Cross *Triticum polonicum* × *T. Elobont*, in England. — 1225. Experiments on the Structure of Common Rice and Gluten Rice, in Japan. — 1226. The Inheritance of Tight and Loose Paleae in *Avena nuda* Crosses, in England. — 1227. Selection of a Type of "Pe-gya" Bean (*Phaseolus lunatus* var.) with a Low Prussic Acid Content, in Burma. — 1228. Behaviour of the Hybrids of the Two Varieties of Peas "Siroendo" and "Sans Parchemin très large Cosse"; Experiments in Japan.
- CEREAL AND PULSE CROPS. — 1229. Alternate Wheats. — 1230. Manitoba Wheat in 1918, in Algeria.
- FORAGE CROPS, MEADOWS AND PASTURES. — 1231. Rhodes Grass (*Chloris Gayana*) at Cuba.
- FIBRE CROPS. — 1232. Cotton Growing in Venezuela. — 1233. The Production of Flax in Italy. — 1234. Experimental Cultivation of Jute (*Corchorus olitorius*), "Malva" (*Urena lobata*) and Sunn Hemp (*Crotalaria juncea*) in Cuba.
- CROPS YIELDING OILS, DYES, TANNINS, ETC. — 1235. Experiments in the Growing and Maturing of Coconuts in Ceylon. — 1236. The Properties and Botanical Origin of "Cunãu".
- RUBBER, GUM AND RESIN PLANTS. — 1237. The Utilisation of Colonial Rubber. — 1238. The Effect of Light in Healing Rubber-Tree Wounds.
- SUGAR CROPS. — 1239. New Varieties of Sugar Cane Produced at Porto Rico. — 1240. The Cultivation of Sugar-Cane in Persia. — 1241. Yellow Sugar Cane ("Mia-vang"), Red Cane ("Mia-ly") and Small Cane ("Mia-lau"), Varieties Grown in Indo-China.
- STIMULANT, AROMATIC, NARCOTIC, AND MEDICINAL PLANTS. — 1242. The Future of the Yemen Coffee Trade. — 1243. Tea in Indo-China. — 1244. Vanilla as a New Product of Porto-Rico. — 1245. Saffron from Kosani, Greece. — 1246. Govap Tobacco and Hoemon Tobacco, the Two Best Indo-Chinese Tobaccos for Native Consumption. — 1247. Introduction of Cinchona into Madagascar.
- VARIOUS CROPS. — 1248. Some Useful Plants of Chili.
- FRUIT GROWING. — 1249. The Pollination of Fruit in Relation to Commercial Fruit Growing.
- VINE GROWING. — 1250. Direct Bearers at the National School of Agriculture of Montpellier (Hérault, France). — 1251. The Effect of Pruning on Grafted Vines.
- FORESTRY. — 1252. The Bark of Scotch Pine and Spruce.

### III. — LIVE STOCK AND BREEDING.

#### a) GENERAL.

- HYGIENE. — 1253. Stock-poisoning Plants of the Range, in the U. S. A. — 1254. The "Enfermedad de los Rastrojos" or "Locura de los Caballos" in the Maize-Growing regions of the Argentine; Means of Control. — 1255. On the Isoanaphylactic Poisoning Due to Certain Immunising Serums. — 1256. The Anaphylactic Nature of Parasitic Poisoning. — 1257. Some Biological and Control Studies of *Gastrophilus haemorrhoidalis* and Other Bots of Horses, in the Dakotas and Montana, U. S. — 1258. Experiments in the Transmission of Trichinae, in the U. S. A. — 1259. Cattle Lice and How to Eradicate Them. — 1260. Avian Malaria Caused by *Plasmodium relictum* (*Proteosoma*); Experiments in Algeria.
- ANATOMY AND PHYSIOLOGY. — 1261. Complementary Studies on the Modification of the Germ Cells of Mammals. Effect of Inhalation of Alcohol Vapour on Guinea Pigs and their Progeny.

## b) SPECIAL.

- POULTRY. — 1262. Acorns as Food for Poultry. — 1263. The Tatu (*Tatusia novemcincta*) as a Pest of Farm-yards in Brazil.
- SERICULTURE. — 1264. Silkworm Rearing in Indo-China.
- FISH CULTURE. — 1265. Complementary Notes on Fish Breeding in Rice Fields, in Madagascar.
- OTHER LIVE STOCK. — 1266. The Fennec Fox in Captivity to Replace the Domestic Cat.

## IV. — FARM ENGINEERING.

- AGRICULTURAL MACHINERY AND IMPLEMENTS. — 1267. Trials of Machines for Cultivating Vineyards Organised at Montpellier and Roche-de-Bran, France, in 1908. — 1268. Tractor Operating Data in the U. S. A. — 1269. The "Fiat" Tractor. — 1270. The Haulage of Ploughs. — 1271. A Tractor Plough. — 1272. The BÉFORT and GAILLARD Electric Ploughing Set. — 1273. The "Once-Over" Quack Grass Killer. — 1274. Motor-saw Mounted on a Hand-cart. — 1275. The MARMIER and CANONNE Apparatus for Drying and Concentrating Liquids at Low Temperatures. — 1276. The Eichenberger Electric Evaporator. — 1277. Review of Patents.

## VI. — AGRICULTURAL INDUSTRIES.

- INDUSTRIES DEPENDING ON PLANT PRODUCTS. — 1178. Analysis of Portuguese Colares' Wines. — 1279. A Study of the Viscosity of Various Colonial Oils. — 1280. Oil of *Jessenia polycarpa* Nuts and *Caryodendron orinocense* Seeds, in Colombia. — 1281. Note on Orange-Pip Oil. — 1282. On the Composition of Fruit Juices. — 1283. The Utilisation of the Colouring Matter of Sweet Sorghum Glumes. — 1284. Papain as a Coagulant for Rubber.
- INDUSTRIES DEPENDING ON ANIMAL PRODUCTS. — 1285. The Effect of Heat on the Citric Acid Content of Milk. — 1286. Method of Counting Bacteria in Raw or Pasteurised Milk. — 1287. A Method for Detecting Bird's Flesh in Meat Preserves.
- AGRICULTURAL PRODUCTS: PRESERVING, PACKING, TRANSPORT, TRADE. — 1288. The Yemen Coffee Trade. — 1289. The Tea Trade in Indo-China. — 1290. The Development and Future of the Silk Products of Indo-China.

## PLANT DISEASES.

## I. — GENERAL INFORMATION.

- LEGISLATIVE AND ADMINISTRATIVE MEASURES FOR THE PROTECTION OF CROPS. — 1291. Measures for the Control of Locusts in Italy.

## II. — DISEASES NOT DUE TO PARASITES OR OF UNKNOWN ORIGIN,

1292. Root Rot of Citrus in the Oasis of Tripoli. — 1293. Disease of the Elm and Nettle Tree, Observed in Italy.

III. — DISEASES DUE TO FUNGI, BACTERIA AND OTHER  
LOWER PLANTS.

- GENERAL. — 1294. Fungi of the Valley of San Martino or the Valley of Germanasco, Piedmont, Italy. — 1295. Fungi from India, Malaya and Africa. — 1296. On the Life History, of the Rose Blotch Fungus (*Actinonema Rosae*), in Great Britain.
- RESISTANT PLANTS. — 1297. Specific Resistance of Different Varieties of Spring Wheat to *Fusarium culmorum*, in Sweden. — 1298. Disease-Resistant Sugar-Canes, in Porto-Rico. — 1299. Direct Bearers Resistant to Diseases and Pests, in France. — 1300. The Influence of Pruning on the Resistance of Grafted Vines to Diseases and Pests.
- MEANS OF PREVENTION AND CONTROL. — 1301. Copper Sulphate and Copper Products in Italy.

- 1302. Disinfection of Seed against *Pleospora graminea*, Injurious to Barley. —  
 1303. Patents for the Control of Diseases and Pests of Plants.  
 DISEASES OF VARIOUS CROPS. — 1304. *Bagnisiopsis Dioscoreae* n. sp., an Ascomycete Para-  
 sitic on Yam, in South Nigeria. — 1305. *Colletotrichum linicolum* n. sp., Injurious to Flax  
 Seedlings, in Ireland. — 1306. *Phoma destructor*, a Deuteromycete Injurious to Tomatoes,  
 in Tunis. — 1307. *Kecthia Chamaecyparissi* n. sp., an Ascomycete Parasitic on the White  
 Cedar, *Chamaecyparis thyroides*, in New Jersey, U. S. A.

## V. — INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

- GENERAL. — 1308. The Coccididae *Pulvinaria platensis* n. sp., *P. flavescens* n. sp. and *P. mi-  
 nuta* n. sp. and their Natural Enemies in Argentina. — 1309. The Origin of the Pink Boll-  
 worm (*Pectinophora gossypiella*), Injurious to Cotton.  
 MEANS OF PREVENTION AND CONTROL. — 1310. The Fennec Fox (*Canis zerda*), Useful for  
 Destroying Injurious Insects. — 1311. Control of Locusts in Capitanata in 1917.  
 INSECTS, ETC., INJURIOUS TO VARIOUS CROPS. — 1312. Influence of the Date of Ear-  
 ing on Damage Done to Spring Wheat by the Dipteron *Contarinia tritici*, in Sweden. — 1313. *Ci-  
 cadula sexnotata*, a Hemipteron Injurious to Wheat, Oats and Barley, in Sweden. —  
 1314. Mite Disease of the Potato, in Hawaii. — 1315. *Gelochia ocellata*, a Microlepidop-  
 teron Injurious to the Beet, New for Italy.

## VI. — INJURIOUS VERTEBRATES.

1316. Preparation of Active Virus Against Field Mice and Method of Applying it in Fields  
 Infested by these Rodents. — 1317. Susceptibility of Field Mice in Apulia to Certain  
 Microorganisms Used to Control These Rodents in the Fields. — 1318. The Biological  
 Control of Field Mice.

## CONTENTS

### SECOND PART: ABSTRACTS.

### AGRICULTURAL INTELLIGENCE.

#### I. — GENERAL INFORMATION.

- DEVELOPMENT OF AGRICULTURE IN VARIOUS COUNTRIES. — 1319. An Agricultural Journey through the Belgian Congo.
- RURAL HYGIENE. — 1320. Tsetse Flies and Fly-Belts, in Africa. — 1321. Utilisation of the Serum of the Horse for Human Nutrition. — 1322. On the Appearance of the Antiscorbutic Substance During the Germination of Seeds.
- AGRICULTURAL EDUCATION. — 1323. Organisation of Public Professional Teaching of Agriculture in France.
- AGRICULTURAL INSTITUTIONS. — 1324. High Council of Agricultural Stations and Laboratories, in France.
- EXPERIMENTAL AND ANALYTICAL WORK. — 1325. Recent Investigations at the Imperial Institute, London.

#### II. — CROPS AND CULTIVATION.

##### a) GENERAL.

- AGRICULTURAL METEOROLOGY. — 1326. The Question of Hail-rods and Storms in the Gironde, France, in 1917. — 1327. Relation between Climate and Cereal Yield in Sweden. — 1328. The Effect of Temperature and other Meteorological Factors on the Growth of Sorghum. — 1329. The Influence of Rainfall on the Fruit Crop in Norway. — 1330. Influence of Nutritive Salts on the Resistance of Plants to Cold.
- SOIL PHYSICS, CHEMISTRY AND MICROBIOLOGY. — 1331. Recent Investigations on Soil Aeration. — 1332. Copper and Zinc as Antagonistic Agents to the "Alkali" Salts in Soils. — 1333. The Effect of Heat on some Nitrogenous Constituents of the Soil. — 1334. Studies on the Correlation between the Production of Carbon Dioxide and the Accumulation of Ammonia by Soil Organisms.
- MANURES AND MANURING. — 1335. Nitrogen Fixation in Manure. — 1336. The Possibility of Obtaining Nitrogenous Fertilisers by Utilising Waste Materials for the Fixation of Nitrogen by Nitrogen-Fixing Bacteria. — 1337. Studies on the Absorption of Ammonia by Superphosphate: "Ammonium Superphosphate". — 1338. Production of Calcium Phosphate at Curacao.
- AGRICULTURAL BOTANY, CHEMISTRY AND PHYSIOLOGY OF PLANTS. — 1339. On the Diffusion of Aluminium Ions in the Plant World. — 1340. Experiments on the Resistance of Plants
- INTERNAT. INST. OF AGRIC. *Internat. Review of Science and Practice of Agriculture.* Year IX, No. 11. Rome, December, 1918.

- to Cold. — 1341. The Influence of the Physiological Condition of the Seed upon the Course of Subsequent Growth and upon the Yield; the Effects of Soaking Seeds in Water. — 1342. The Influence of Temperature on the Germination of the Seeds of the White Mulberry.
- PLANT BREEDING. — 1343. Mutation Observed in a Pure Strain of Two-Rowed Barley (*Hordeum distichum* L.) in Bavaria. — 1344. The Relation between Colour and other Characters in Certain Avena Crosses. — 1345. Methods for Selecting and Improving the Cotton Plant in Egypt. — 1346. Apple Selection in Canada. — 1347. Selection of the Valencia Orange in California, U. S. A.
- AGRICULTURAL SEEDS. — 1348. Measures taken in Hungary for the Production of Sugar Beet Seed.
- CEREAL AND PULSE CROPS. — 1349. Tests of Some Spring Wheats (Manitoba, Aurora and Marquis) in Vaulcuse, France. — 1350. Cultural Tests with Sol II Wheat in South Sweden. — 1351. Pansar Wheat in South Sweden. — 1352. The Rational Distribution of the Different Varieties of Rye in Sweden. — 1353. Commercial Pulse Crops.
- STARCH CROPS. — 1354. The Production of Tapioca in the Dutch East Indies.
- FIBRE CROPS. — 1355. The Possibility of Developing Cotton-growing in Cambodia. — 1356. The Deterioration of Egyptian Cottons and Means of Remedying it. — 1357. Four Large Scale Textile Crops: Jute, Crotalaria, Hibiscus, Sesbania, with a Note on Abroma. — 1358. Observations on Ramie in Indo-China. — 1359. Agave Cultivation in Tropical and Intertropical Countries, Especially Madagascar.
- STIMULANT, AROMATIC, NARCOTIC AND MEDICINAL PLANTS. — 1360. The Production of Plant Essences in the Dutch East Indies. — 1361. The Cultivation of Pyrethrum in Switzerland.
- PLANTS YIELDING OILS, DYES AND TANNINS. — 1362. The Production and Price of Orchil. — 1363. The Production of Dur-dur in the Dominican Republic.
- RUBBER, GUM AND RESIN PLANTS. — 1364. Comparative Results of the Growth of *Hevea*, *Castilloa* and *Funtumia* Rubber Trees at Tobago.
- FORESTRY. — 1365. Effect of Grazing upon Western Yellow-Pine Reproduction in the National Forests of Arizona and New Mexico, U. S. A. — 1366. National Parks in Spain.

### III. — LIVE STOCK AND BREEDING.

#### a) GENERAL.

- HYGIENE. — 1367. On Ocular and Locomotor Troubles in Equine Trypanosomiasis, in Morocco. — 1368. On the Mortality from Trypanosomiasis of Dromedaries. — 1369. Endoglobular Parasites of the Horse in Morocco. — 1370. The Etiological Cause of Granular Dermatitis of the Horse. — 1371. The First Tests of Vaccination against Epizootic Lymphangitis. — 1372. Distomatosis and Glycosuria in Cattle, in Brazil. — 1373. The Presence of the Virus of Rabies in the Spleen. — 1374. The Control of the Blow-Fly and the Sheep Maggot Fly in Queensland. — 1375. On a New Disease of the Dog, in Senegal. — 1376. Description of a Bacterium which Oxidises Arsenites and of Another which Reduces Arsenates, Isolated from a Cattle-Dipping Tank in South Africa.
- ANATOMY AND PHYSIOLOGY. — 1377. Elimination of Arsenic after Ingestion by, and Injection into, Live Stock, and after Absorption through the Skin by Dipping.
- FEEDS AND FEEDING. — 1378. Researches on the Utilisation of Inosite by the Animal Organism. — 1379. The Dietary Qualities of Barley. — 1380. The Cleaning and Crushing of Locust Beans, and the Removal of their Husks. — 1381. Value of Bulbs as a Cattle Food; Investigations in the Netherlands.
- BREEDING — 1382. Crosses between the American Bison, the European Bison and Domestic Cow Made in the Zoological Garden of Askania-Nova (Government of Tauride, South Russia).

## b) SPECIAL.

- CATTLE.**—1383. Comparative Yield of Cattle Before and After Fattening. — 1384. An Experiment in War Time Beef Production in Great Britain.
- SHEEP.**—1385. "Woolless" Sheep as Butcher's Animals in Cuba.
- PIGS.**—1386. Substitutes in Swine Feeding, in Canada. — 1387. Fish Meal as a Feed for Swine.
- POULTRY.**—1388. The Part Played by the Egg Shell of the Hen in the Formation of the Chicken's Skeleton During Incubation. — 1389. Final Report of the Fourteenth Egg-Laying Competition Held at the Queensland Agricultural College, Gatton, from April 1, 1917 to March 31, 1918.
- BEE KEEPING.**—1390. The Artificial Feeding of Bees with Pollen.
- SERICULTURE.**—1391. The Creation of an Interministerial Silk Committee in France. — 1392. Influence of the Breed of the Eggs on the Cleanness of Raw Silk.
- OTHER LIVE STOCK** —1393. On the Possibility of Rearing the Manatee as a Food Animal in French West Africa.

## IV. — FARM ENGINEERING.

- AGRICULTURAL MACHINERY AND IMPLEMENTS.**—1394 The Function of Agricultural Engineers as regards the Makers of Power-Farming Machinery. — 1395. A Tractor School in Illinois, U. S. A. — 1396. Restrictions on the Manufacture of Farm Implements in the U. S. A. — 1397. National Power-Farming Show at Salina, Kansas, U. S. A. — 1398. Tests of the Cleveland Tractor at Montpellier, France. — 1399. Couplings for Tractors. — 1400. Harvesting with a Tractor. — 1401. Simultaneous Harvesting and Breaking-up of the Stubble with a Tractor. — 1402. Log Saw. — 1403. An Improved Pasteurising Plant. — 1404. Equipment for the Commercial Evaporation and Drying of Fruit, in the U. S. A. — 1405. The Installation and Equipment of an Egg-Breaking Plant. — 1406. Review of Patents.

## VI. — AGRICULTURAL INDUSTRIES.

- INDUSTRIES DEPENDING ON PLANT PRODUCTS.**—1407. On De-foxing Wines. — 1408. On a Water Bacterium Living in Bitter Wines that can Dehydrate Glycerine; Glycero-Reaction. — 1409. Sudan Dura as a Brewing Material. — 1410. The Potato Starch Industry in Italy. — 1411. War Syrups. — 1412. Commercial and Domestic Fruit Drying. — 1413. Opium Wax. — 1414. Acetic Acid Manufacture on Rubber Estates. — 1415. Mechanical Coagulation of Rubber. — 1416. The Utilisation of Coal Dust for Heating Greenhouses.
- INDUSTRIES DEPENDING ON ANIMAL PRODUCTS.**—1417. The Refractometric Estimation of Milk Sugar. — 1418. Free Lactic Acid in Sour Milk. — 1419. "Renovated" Butter. — 1420. The Manufacture of Casein from Buttermilk or Skim Milk. — 1421. The Installation and Equipment of an Egg-Breaking Plant.
- AGRICULTURAL PRODUCTS: PRESERVING, PACKING, TRANSPORT, TRADE.**—1422. Microorganisms and Heat Production in Silage Fermentation. — 1423. The Cork Industry.

## PLANT DISEASES.

## III. — DISEASES DUE TO FUNGI, BACTERIA AND OTHER LOWER PLANTS.

- GENERAL.**—1424. New and Rare British Fungi.
- MEANS OF PREVENTION AND CONTROL.**—1425. Patents for the Control of Diseases and Pests of Plants.

DISEASES OF VARIOUS CROPS. — 1426. Diseases Reported on Wheat in Java. — 1427. *Uromyces pedicellatus* n. sp., a Rust Injurious to *Eragrostis abyssinica* and *E. curvula* in the Transvaal — 1428. *Cronartium occidentale* n. sp., a Rust Injurious to *Pinus edulis*, *P. monophylla*, *Ribes* spp. and *Grossularia* spp. in Colorado and Arizona, U. S. A.

#### IV. WEEDS AND PARASITIC FLOWERING PLANTS.

1429. Orchid Parasitic on the Leguminous Plant *Caesalpinia coriaria*, in the Dominican Republic. — 1430. *Sorghum halepense*, a Weed in Porto Rico.

#### V. — INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

MEANS OF PREVENTION AND CONTROL. — 1431. Enemies of the Chinch-bug (*Blissus leucopterus*), Observed in Illinois, U. S. A. — 1432. Parasites of *Porthetria dispar* (Gipsy Moth) in Spain. — 1433. *Apanteles lacteicolor* and *Meteorus versicolor*, Hymenoptera Parasitic on the Brown-Tail Moth (*Euproctis chryssorhea*), Imported into the United States from Europe.

INSECTS, ETC., INJURIOUS TO VARIOUS CROPS. — 1434. The Control of *Cylas formicarius*, a Coleopteron Attacking Sweet Potatoes at Porto Rico. — 1435. *Pectinophora gossypiella*, a Microlepidopteron Injurious to Cotton in Egypt. — 1436. Observations on the Coleopteron *Lasioderma serricornis*, and the Lepidopteron *Setomorpha margalaestriata*, Injurious to Tobacco in the Dutch East Indies. — 1437. *Clytus devastator*, a Coleopteron Injurious to Citrus and other Plants, in Cuba and Florida. — 1438. Pests of Stored Food-stuffs in Java.

# WEIGHTS, MEASURES AND MONEY OF THE VARIOUS COUNTRIES WITH THEIR ENGLISH EQUIVALENTS.

1 Archine (Russia)	= 27.99961 inches
1 Ardeb (Egypt)	= 5.44435 bushels
1 Ardeb of wheat (Egypt)	= 2.95264 cwt.
1 Ardeb of hulled maize (Egypt)	= 2.75580 cwt.
1 Ardeb of barley (Egypt)	= 2.36211 cwt.
1 Ardeb of undecorticated rice (Egypt)	= 5.72812 cwt.
1 Ardeb of decorticated rice (Egypt)	= 3.83843 cwt.
1 Arpent (Canada)	= 0.84501 acre
1 Are [100 square metres]	= 107.63915 square feet
1 Arroba (Brazil)	= 33.06951 lbs.
1 Arroba (Cuba, Guatemala, Paraguay, Peru)	= 25.35841 lbs.
1 Arroba (Mexico)	= 25.36697 lbs.
1 Bale of cotton (Brazil)	= 396.83415 lbs.
1 Bale of cotton (United States)	= 4.46431 cwt. (gross wt.)
1 " " " " "	= 4.26788 cwt. (net wt.)
1 Bale of cotton (India)	= 3.57145 cwt.
1 Barrel of wheat flour (Canada, United States)	= 1.75001 cwt.
1 Bar, see Millier	
1 Bow (Java, Dutch Indies)	= 76.36998 square feet
1 Bushel (United States)	= 0.96896 bushels
1 Bushel of oats (United States)	= 32 lbs.
1 Bushel of oats (Canada)	= 34 lbs.
1 Bushel of wheat and potatoes (United States)	= 60 lbs.
1 Bushel of barley (Canada, United States)	= 48 lbs.
1 Bushel of raw rice (United States)	= 45 lbs.
1 Bushel of rye, hulled maize, linseed (Canada, United States)	= 56 lbs.
1 Cadastral arpent (Hungary)	= 1.42201 acres
1 Cental (United States)	= 100 lbs.
1 Centiare [10 square metres]	= 10.76392 square feet
1 Centigramme	= 0.15432 grains

The Forest Industry in Sweden

by

E. AROSENIUS

*Departmental Head at the Swedish Royal Central Office of Statistics.*

For hundreds of years timber has held an important place among Swedish exports, but it was only towards the middle of the 19th. century that the exportation of this article increased considerably with the demand for sawn timber rather than unhewn timber (spars, etc.) or squared timber (beams, quarters).

In 1913 the values of the woods exported by Sweden were as follows:

Rough hewn timber, . . . . .	£	1 150 059. 12. s. 2 d.
Sawn, unplanned timber . . . . .	"	7 598 137. 11. 2
Planed and other worked woods (including joinery). . .	"	3 114 454. 11. 1
Wood pulp for paper . . . . .	"	5 489 529. 6. 9
Total . . . . .	£	1 735 2181. 1. 2

This sum represented about  $\frac{2}{5}$  ths. of the total value of Swedish exports.

The raw materials used in the Swedish saw-mills consist essentially of soft wood — Scotch pine and spruce. About  $\frac{2}{5}$  ths. pine and a little more than  $\frac{2}{5}$  ths. spruce are used for making planks, and boards (planed or unplanned). Staves are made chiefly with wood of deciduous trees.

FLOATING THE WOOD. — Although much wood may be carted directly, or sent by rail, from the place where it is felled to the saw-mills, floating is the most important means of transport, and the high place occupied by Sweden in the international timber trade is primarily due to its many water-courses well adapted for floating wood. The largest rivers of northern

Sweden rise in the high mountains and are sufficiently well fed by the ice and snow for wood to be floated down them throughout the summer. In southern Sweden, on the other hand, it often happens that there is only sufficient water for floating when the rivers are swollen in the spring, or that mills and other works prevent the use of this method. Nevertheless, floating is very common, particularly in the north.

Besides the considerable economy in labour and cost of transport, floating has an additional advantage in that wood which has been some months in the water does not warp so easily after sawing as wood sawn immediately after being cut, and has a more uniform colour. On the other hand, the washing of the resin which takes place during floating decreases the life of the wood.

In order that floating may be carried out without hinderance and that the largest quantities of wood may be transported by the water available, the water-courses, especially the smallest ones, have been dredged and provided with various constructions such as dikes or sluices to regulate the level of the water in the reservoirs, iron or wooden pipes for guiding the wood in shallow rapids, bars for preventing the wood from catching on to the banks, chains for collecting and sorting the wood. For transport on lakes or other smooth water the logs are enclosed, sometimes many thousands at a time, in a frame of large trunks joined together.

These works are carried out by the owner of the forest if he owns both the water used for floating and the wood to be transported, but, as a rule, the streams are public transport ways, generally divided by the State, each being administered by a "Floating Association", which takes charge of the floating in return for the payment of a tax fixed by the provincial government, the expenses, including the amortization of the cost of installation, being divided amongst the owners of the wood floated. In proportion as this amortization progresses, the cost of floating naturally diminishes. The cost varies considerably according to the amount of water available and the quantity of wood to be floated; on large water-courses it amounts to about 0.124 *d.* to 0.496 *d.* per mile per cubic metre (1), but on small water-courses it is much higher. The total length of the water-courses available for floating in Sweden is estimated at 16 146 miles, of which 14 283 are in the north of the country, above the river Dalälven.

**TIMBER SAWING.** — Although carried out since the middle ages, the sawing and exportation of timber only developed to a large extent toward the middle of the 19th. century, when a more liberal commercial legislation, the suppression of export dues, and, at the same time, the increasing demand for sawn wood, gave a great impulse to this industry. Its development was also favoured by the abundant water power available. Thus, a fairly large number of saw-mills with multiple frames were built in the northern, wooded parts of Sweden ("Norrländ"), particularly near waterfalls and the coast. The fact that it was impossible to build these mills actually

(1) 1 cubic metre = 35.317 cubic feet

on the coast was a drawback, since, in order to ship the sawn wood, it was necessary, either to cart it, tow it to a neighbouring port, which was fairly expensive, or also to float it, which spoilt the appearance and quality of the goods.

In this respect a complete revolution was effected when *steam saw-mills* were built *on the coast*. These gave the following advantages: — abolition of the long and costly transport from the mill to the port; increased capacity of production; better products; abolition of interruptions in the work in water saw-mills caused by freezing in winter and lack of water in summer. The first of these steam mills was built in 1851 at Vifsta, near the town of Sundsvall, and their number increased rapidly.

According to the latest available data, there were in Sweden, in 1913, 1053 industrial saw-mills and machine planing works, without counting a certain number of small mills for home use, worked either by hydraulic or steam power. The total cost of building the former has been estimated at 199 024 488 *crowns* (1 *crown* = 1s. 1d. *at par*), thus greatly exceeding the capital required for erecting any other kind of works. The value of the products may be placed at 216 million *crowns*, including the wood and charcoal sold; to this should be added 1 124 684 *crowns*, which represent the value of materials worked.

The number of workmen employed in the industry was 44 150; 1659 frames and 905 planing machines were used. As motive power were used: water-wheels, up to 1040 HP.; water-turbines of 14617 HP.; steam engines of 82 135 HP.; steam turbines of 2 246 HP.; oil and gas engines of 476 HP. Most of this power was used directly for working the machine saws, and the rest (21 949 HP.) for generating electricity for the motors.

The edges and ends of the wood sawn are trimmed with a circular saw, worked either by hand or by electric motor. This only applies to large mills, which have moving platforms worked by electricity for the automatic transport of the wood from the piles to the saws.

Sawn pine wood is often divided into five classes of different qualities, a very delicate operation. On the other hand, most of the spruce wood is shipped without being classed.

Many mills have planing works attached to them, for, in Sweden, planing rarely forms an independent industry, as is usually the case in Norway.

The chief machine saw-mills are those of Mo, Kramfors, Vifsta (the oldest), Skönvik, Bergvik, Korsnäs (or Bomhus) and Skutskär. Kramfors is on the navigable river Älgermanälven, along the lower course of which are numerous saw-mills. All the other places follow each other from the north to the south in the order in which they are named, along the coast of the gulf of Bothnia. There is no doubt that the Korsnäs and Skutskär mills, between Gevle and the mouth of the Dalälven, are the largest in Europe. They have 30 and 24 frames respectively, and each ships annually sawn timber wood estimated at 40 000 Petrograd *standards* (1 *standard* = 165 cubic feet for sawn timber).

In northern Sweden (provinces to the north of the Dalälven) there are only about a third of all the mills in the country, but they supply about  $\frac{2}{3}$  of the

of the total production. The northern part of the country has a still greater preponderance in exportation, for, in the more populous southern part, a larger fraction of the products of the mills is sold for home consumption.

In 1913 the total production of the Swedish saw-mills was 6 853 455 cubic metres, distributed as follows :

Unplaned planks and boards . . . . .	1 693 990 cubic metres
Planed planks . . . . .	1 210 159
Pieces of planks and boards . . . . .	358 353
Leaves and laths . . . . .	99 383
Planks for cases . . . . .	302 678
Staves . . . . .	188 397

6 853 155 cubic metres

In addition to these there are some smaller articles, of which the statistics give the value but not the quantity.

In 1913, 6 877 825 cubic metres of rough, squared and sawn wood were exported. Table I shows the distribution per category and country to which it was exported. During the period 1906-1910, the average amount exported annually was 6 052 000 cubic metres.

Table I shows that the net amount exported in 1913 almost equalled the total production of the mills, but it must be noted that it also includes unhewn wood. In 1914 and 1915 the timber trade was adversely affected on account of the war, and exportation decreased for most kinds of timber. For sawn timber this decrease was about  $\frac{1}{5}$  th. of the quantity exported in 1913.

TABLE I. — *Quantities of rough, squared and sawn timber exported from Sweden in 1913 (in cubic metres).*

\* Including boards for packing-cases

A branch of the timber industry which has recently inspired a certain nervousness, is the exportation of mine props, as it is feared, not without

reason, that this may depopulate the forests. The felling of wood for such props would have no harmful effect if only trees of medium value which might be considered as useless for the rational preservation of the forest, were used ; on the other hand it becomes very serious when, as often happens, whole young plantations are felled.

Mine props are chiefly exported from southern Sweden, which supplies the greater part of the wood used for this purpose ; Norrland (northern Sweden) in particular, also exports a large amount. These props are exported almost exclusively to England.

**WOOD PULP AND CELLULOSE INDUSTRY.** — This, together with timber-sawing, though a little later, has developed into a flourishing industry, taking 2nd. place as regards value of production. As is well known, wood pulp is divided into two principal varieties according to the method of preparation : 1) *mechanical*, obtained by disintegrating the wood by a runner, under a continuous stream of water ; 2) *chemical*, or wood cellulose, obtained by disintegrating the wood by chemical solutions : *a*) sodium sulphate (sulphate cellulose) ; *b*) calcium or magnesium bisulphite (bisulphite cellulose). On the other hand, *semi-chemical* wood-pulp is that obtained by first boiling the wood in water, so as to eliminate part of the incrustation, then breaking it up by a mechanical process. This pulp, sometimes called unbleached (brown), is very strong, but, owing to its dark colour, cannot be used for fine paper.

As raw material, spruce is especially used in Sweden (it is used almost exclusively for bisulphate pulp), and also a little pine and aspen wood.

The first mechanical wood-pulp factory was founded in 1857 at Trollhättan. The manufacture of chemical pulp is of more recent date, but has surpassed that of mechanical pulp. The wood-pulp industry, long confined to the south and west of Sweden, has spread greatly, during the last decades, in Norrland and Dalecarlie, where it has been adopted by many large saw-mills in addition to their own principal industry, thus allowing them to utilise small pieces of wood and waste, and to effect the necessary thinning of their forests with greater economic advantage. The development of the cellulose industry has been aided of recent years by a better utilisation of the by-products : alcohol from the waste waters of bisulphite cellulose, oil of turpentine, etc.

It seems that the manufacture of alcohol might be developed ; in 1913, 4 million litres at 50 % were produced, but it has been estimated that the Swedish wood-pulp factories could produce annually 26 million litres of 100 % alcohol.

In 1913 there were in Sweden 167 wood-pulp factories distributed as follows :

Product	No. of factories
Mechanical wood-pulp . . . . .	83
Mechanical pulp and chemical pulp. . .	17
Chemical sulphate pulp . . . . .	17
Chemical bisulphite pulp . . . . .	49
Sulphate pulp and bisulphite pulp. . .	1
	<hr/> 167

The production (expressed in dry matter) was estimated at 1 186 577 tons, of which 326 098 tons were mechanical pulp, 705 099 tons bisulphite pulp and 155 430 tons sulphate pulp. The total value of this production was about 126 million *crowns*.

During the year 1 009 358 tons of paper pulp were exported ; this corresponded to 847 137 tons of dry matter. With the exception of a negligible quantity of rag pulp, this was all wood pulp, divided as follows into the various categories :

Mechanical pulp. . .	{	moist . . . . .	261 049	metric tons
		dry . . . . .	59 198	
Bisulphite pulp. . .	{	bleached . . . . .	20 690	
		unbleached moist . . . . .	58 548	
		» dry . . . . .	508 134	
Sulphate pulp. . . .	{	bleached . . . . .	10 972	
		unbleached moist . . . . .	1 846	
		» dry . . . . .	85 921	
			<hr/> 1 009 358	metric tons

**CHARCOAL.** — This has been prepared in Sweden since remote times, and has always found regular markets near the place in which it is produced. It is used for iron smelting (blast furnaces and forges), for which it is necessary.

It is prepared by the old pile-method, but also sometimes in ovens, either in metallurgical works or in other places favourably situated for the collection of wood and the forwarding of the charcoal. The manufacture of charcoal on a large scale in piles in the forests is due to the facility with which it may be transported in winter on sledges, thus avoiding the necessity of constructing costly ways of communication. Where it is necessary to transport large quantities of charcoal to metallurgical works by means of floating, it is best prepared in ovens. Many saw-mills of northern and southern Sweden prepare charcoal with their wood waste, either in piles or in ovens.

Recently the charcoal industry has begun to compete with the wood-pulp industry in the purchase of raw materials. This, together with the rise in wages, has caused a notable rise in the price of charcoal, which has necessitated a restriction of its use by applying various new metallurgical methods, which have succeeded fairly well. Nevertheless, charcoal is still a very important commercial article.

The woods used are spruce and pine. The charring is carried out in either vertical or horizontal piles, so called according to the way in which the wood is piled up. Two parts of wood (loosely piled) give about one part of charcoal. Ovens give a slightly higher yield than piles, but the product is inferior, for it is estimated that 10 parts in volume are required to produce the same amount of heat as nine parts of piled charcoal. On the other hand, charring in ovens gives various by-products: methyl alcohol, acetic acid, essence of turpentine, tar, etc. Specially designed small

ovens are used to collect the tar and oil of turpentine produced during the charring of dry pine stumps.

The following data are available with regard to the production of charcoal in 1913:—

Method of Preparation	Amount of charcoal obtained in bushels
Forest wood charred in ovens . . . . .	8 063 000
Wood waste . . { charred in piles . . . . .	29 166 000
{ charred in ovens . . . . .	1 323 000
	<u>38 552 000</u>

There are no exact statistical data on the quantity of charcoal prepared in piles in the forests, but, according to the following calculation it may be estimated at about 75 502 000 bushels.

Total amount of charcoal used by metallurgic works . .	117 355 000 bushels
Deduct: Charcoal imported from Finland and Norway . .	<u>3 301 000</u>
Total amount of charcoal produced in Sweden . . . . .	114 054 000
Deduct: Production of charcoal known from statistics . .	<u>38 552 000</u>
Amount of charcoal prepared in piles in the forests . .	75 502 000

PRODUCTS FROM THE DRY DISTILLATION OF WOOD. — Formerly the preparation of wood tar was an important industry in Sweden as it was one of the principal exports. At the present day this industry is carried out only in the two most northern provinces, and the tar produced is exported chiefly from the town of Umeå. For its manufacture large funnel-shaped utensils, open at the top, are used. The wood is piled up in them and covered with earth; the tar runs out from underneath. Various saw-mills have tar ovens from which are obtained, not only tar, but also the other products of dry distillation: methyl alcohol, acetic acid, acetone, etc.

Table II gives the data concerning the importation and exportation of these various products in 1913.

TABLE II. — *Importation and exportation of the products and by-products of the dry distillation of wood, in 1913.*

The important place occupied in Swedish imports by that of wood of various kinds has already been pointed out. A comparison of the wood exports of Sweden and other countries is difficult, as are all international statistics on account of the different methods of calculation in use in the various countries. Nevertheless, the data contained in Table III, taken from the official statistics of each country, shows fairly well the place held by each of the principal wood-exporting countries.

TABLE III. — *Wood exports of the principal exporting countries from 1906 to 1913.*

Country	1908	1909	1910	Average annual value from 1906 to 1910	1911	1912	1913

Canada* . . . . .	9 173 434	10 994 502	10 682 902	10 270 158	9 634 111	10 192 763	10 268 632

\* In these two countries the commercial years do not coincide with the solar years.

The high figures of the United States timber exports may probably be explained partly by the fact that they also include valuable wood (oak and other deciduous trees).

The exporting countries have only been compared with regard to the *value* of their exports, as it is not possible to make an exact comparison of the *amount of wood* exported. All that can be said on this point is that, in Europe, the first place has been held alternately by Russia (without Finland) and Austria-Hungary, then during the last two or three years, by Sweden.

SECOND PART.  
ABSTRACTS

AGRICULTURAL INTELLIGENCE

GENERAL INFORMATION.

1 -- *International Yearbook of Agricultural Legislation, 7th. Year (1916).* — INTERNATIONAL INSTITUTE OF AGRICULTURE, Rome 1917.

LEGISLATIVE  
AND ADMINIS-  
TRATIVE  
MEASURES

The seventh volume of the *International Yearbook of Agricultural Legislation* has just been published by the International Institute of Agriculture. It contains, systematically classified, all the laws relating to agriculture in the various countries. This publication is, therefore, of great interest under the present war conditions.

The *Yearbook* is divided into 11 parts : — The first (Statistics), second (Commerce), fourth (Industries depending on plant products), and fifth (Industries depending on animal products) are of the greatest interest to those who wish to follow, in all its details, the legislative movement with regard to foodstuffs brought about by the European crisis. In these divisions of the *Yearbook* is included everything bearing on : Statistics of stocks and crops ; trade in cereals and supplies in general ; trade in other vegetable foodstuffs ; seed trade ; fertiliser trade ; trade in oil-yielding fruits ; trade in textile plants and tobacco ; trade in live stock and animal products ; trade in agricultural machinery ; facilities granted for imports and restrictions laid on exports ; measures for forestalling and dealing with the rise in prices ; dishonest competition and fraud in trade ; legal measures for regulating commercial contracts ; measures for preventing the advance sale of crops ; transport of vegetable and animal products ; regulation of industries concerning plant products and chemical fertilisers ; regulation of crops during the war.

The 7th. part, devoted to plant diseases, weeds and animals injurious to agriculture, gives the text of the Egyptian laws concerning : the protection of plants against diseases from abroad, diseases of fruit trees, the de-

struction of the cotton bollworm, orange pest (*Aspidiotus aonidium*), the text of the Soudan order concerning the destruction of locusts. It also includes : the orders of the French Government with regard to the sale and use in agriculture of arsenical compounds ; an Australian (Victoria) law concerning the sale of anti-cryptogamic products and insecticides ; the order for carrying out the Italian law of June 26th., 1913, No. 881, on plant diseases ; the various Italian decrees for the control of field mice.

The *Yearbook* contains many provisions with regard to agricultural co-operation, insurance and credit.

The part devoted to rural property includes the strictly legal measures defining and regulating the rights of property, and the charges on real estate held either in usufruct or by way of security ; the provisions to be observed in the transmission of these rights and in the determination of the title to ownership, especially in the interest of third parties ; the method of procedure with regard to attachments on movable goods and real estate. It also contains the provisions of a more specially social and political nature, which tend to act directly on the distribution of real estate and to allow a more complete use being made of the land.

With regard to the less important measures the *Yearbook* only gives the original title together with the French translation ; for the others, either extracts from the text or else the whole text is given. There is an analytical introduction of 77 pages published in five languages, French, English, Italian, Spanish and German, which gives a summary of the whole volume (1250 pages). There is also a chronological index of the countries and an alphabetical subject index.

#### RURAL HYGIENE

2 - **A Biological Analysis of Pellagra-Producing Diets: I) The Dietary Properties of Mixtures of Maize Kernel and Beans.** — MC COLLUM, E. V. and SIMMONDS, N., in the *Journal of Biological Chemistry*, Vol. XXXII, No. 1, pp. 29-61, 24 charts. Baltimore, Md., October, 1917.

The first phase of the studies on nutrition undertaken by the authors and their collaborators at the Laboratory of Agricultural Chemistry of the University of Wisconsin, Madison (1), dealt with the cause of nutritive failure in animals restricted to diets of proteins, carbohydrates, fats and inorganic salts, all the foods being chemically pure. After a careful consideration of the work of HOPKINS, STEPP, and FUNK, the authors came to the conclusion that these mixtures were lacking in two substances, or groups of substances, indispensable to the preservation of animal life.

(1) HART, E. B., MC COLLUM, E. V., STEENBOCK, H. and HUMPHREY, G. C., *Wisconsin Agricultural Experiment Station, Research Bulletin* 17, 1911 ; HART and MC COLLUM, *Journal of Biological Chemistry*, 1914, Vol. XIX, p. 373 ; MC COLLUM and DAVIS, *Ibid.*, 1915, Vol. XX, p. 415, Vol. XXIII, pp. 181 and 231 ; MC COLLUM, SIMMONDS and PITZ, *American Journal of Physiology*, 1916, Vol. XII, pp. 333 and 361 ; MC COLLUM and KENNEDY, *Journal of Biological Chemistry*, 1916, Vol. XXIV, p. 491 ; MC COLLUM, SIMMONDS and PITZ, *Ibid.*, 1916, Vol. XXV, p. 105 ; HART, MILLER and MC COLLUM, *Ibid.*, 1916, Vol. XXV, p. 239 ; MC COLLUM, SIMMONDS and PITZ, *Ibid.*, 1916-1917, Vol. XXVII, pp. 153 and 211 ; MC COLLUM, *Journal of the American Medical Association*, 1917, Vol. LXVIII, p. 1379 ; MC COLLUM, SIMMONDS and PITZ, *Journal of Biological Chemistry*, 1917, Vol. XXIX, pp. 341 and 521 ; Vol. XXX, p. 13 ; MC COLLUM and PITZ, *Ibid.*, 1917, Vol. XXXI, p. 229. (Ed.)

One of these (fat-soluble A), is soluble in fats, and found in its most concentrated form in butter fat and egg yolk fats. The second substance is never associated with fats in foods, but is always present in natural foods in relative abundance. It is easily administered in experimental rations by the addition of alcoholic extracts of natural foods, but it is also soluble in water. This is called by the authors water-soluble B.

The authors showed phosphorised proteins to have no superior value to those containing no phosphorus and it is now known that a long list of substances (including complex lipoids, pigments, sulphatides of the nerve tissues, components of the various prosthetic groups) with which the body proteins are combined, are produced within the tissues and do not need to be supplied with the food. The synthetic capacity of the animal cells has thus been shown to be immeasurably greater than had been supposed, but all the evidence still points to the fact that nearly all the amino-acids formed during the digestion of proteins are indispensable components of the diet. Moreover, the animal tissues are very dependent upon certain of the finer stereochemical structures in both the amino-acid and carbohydrate groups which serve them as food complexes.

The second part of the studies was an examination, one by one, of several typical representatives of the classes of natural food substances, such as the seeds, leaves, fruits and tubers of plants. The exact nature of the additions of the factors A and B necessary to complete one of these food substances from the nutrition standpoint was shown. Some of these studies are still in progress.

The results show that serious errors may be made in the choice of foods, especially by the poor. Beri-beri, scurvy, rickets and pellagra, have all been proved to be due to defective diet, although different opinions still prevail as to the etiology of the last disease. FUNK attributed each of the above-mentioned syndromes to the absence of a specific chemical substance which he called "vitamine". The work of the authors and their collaborators on the nature of the dietary deficiencies of any natural food-stuffs has lead them to conclude that, under the present existing conditions, there are three other dietary factors causing malnutrition in both man and animals.

The third part of the studies, described in the present papers, consisted in a close experimental enquiry into the properties, with regard to the several dietary factors, of the diets usual in human nutrition and derived from all the more important food materials (except milk and eggs) in common use in the United States. Eggs, and more particularly milk, are a wonderful safeguard in human nutrition, and a valuable addition to all rations used in animal production.

In a previous paper were discussed the points of resemblance in the dietary properties of seeds in general as contrasted with those of the leaf of the plant. The most important generalisations which can be made concerning the seeds as a group are the following:—

1) None of the seeds studied, when forming the sole source of nutriment, can produce growth or prolonged well-being in a young animal. Mixtures of seeds are more satisfactory

for keeping animals in a good state of health, without growth, than seeds of a single species as a sole food; mixtures of seeds fed with distilled water (salt-free) will not support growth in young rats.

2) The inorganic content of each of the seeds studied (wheat, oat, maize, rice, wheat germ, bean, pea, flax and millet) is so constituted with respect to the total quantity and relative quantities of its constituents that certain salt additions are essential before growth can proceed in young animals. This applies both to mixtures of seeds and to seeds of a single variety.

3) The seeds of wheat, oat, maize, rice, bean and pea are too low in their content of a dietary essential, the nature of which is still unknown, to supply the needs of a young animal during growth. This substance is present in abundance in certain fats, such as butter and egg yolk fats, and the fats extracted by solvents from animal organs, such as the liver and kidney, free from visible fats. It is also found in abundance in the leaves of plants and in considerable quantities in the seeds of flax and millet. The authors have provisionally called this dietary essential "fat-soluble A". It is not extracted from plants with the fats by solvents such as ether, chloroform, benzene or acetone, and is, therefore, not found in any fats or oils of plant origin. Hot alcohol does not remove it from plant tissues.

4) All the seeds studied contain protein mixtures of a relatively poor quantity when the proteins of a single kind of seed serve as the sole source of proteins.

5) Each of the seeds studied can be supplemented by highly purified protein, pure inorganic salts, and one of the growth promoting fats, so as to form a satisfactory ration for growth and maintenance. 15 to 20 % of any one of the seeds mentioned, when fed with a mixture of purified food substances, will serve to supply all unidentified dietary factors soluble in water or alcohol. So far there is evidence of only one such indispensable substance — water soluble B — which is never associated with fats of either animal or plant origin.

6) Generalising from studies of three types, clover, alfalfa and cabbage, the leaf differs from the seed in having a high content of inorganic elements, and is particularly rich in those elements, calcium, sodium and chlorine, which are found in but small amounts in the seed. The leaf is much richer in the fat-soluble A than are such seeds as wheat, oat, maize, bean and pea. Leaf and seed supplement each other with respect to these two dietary factors. Since, in many cases at least, the leaf and seed mixtures have been shown to yield adequate protein mixtures, there is probably always some supplementary relationship between them with respect to the amounts of the various amino-acids which they yield on digestion.

In the studies quoted no systematic data were given showing the dietary properties of mixtures of cereal and legume seeds. The present paper describes the nature of the purified food additions which must be made to combinations of the maize kernel and the white (navy) bean in various proportions in order to make these seed mixtures dietetically complete. The experiments described aimed at making clear the value of each dietary factor in the maize bean mixtures as compared with several of the most important seeds, especially maize, wheat and navy bean. These last were thoroughly studied separately so as to show the nature of their dietary deficiencies.

The results, obtained with rats, are given in a set of charts and summarised as follows: —

1) The two seeds mixed, as when separate, contain too small an amount of fat-soluble A to induce optimum well-being in growing animals.

2) The mixtures of maize and beans furnish a great abundance of the second unidentified dietary factor, water soluble B.

3) The most satisfactory protein mixture obtainable with these two seeds consists in about 80 % of maize and 20 % of bean. This protein mixture has a slightly higher biological value than an equivalent amount of maize kernel proteins. In smaller quantities (e. g. 7 % of the food mixture) the proteins of the wheat and the maize kernel have about the same value. When a ration is properly constituted with regard to other factors and contains 9 % of wheat proteins, growth may be practically normal over a period of 5 months, after which an injurious effect is apparent in stunting and lack of fertility. It is highly probable that if the maize protein content were raised to 12 %, approximately normal growth would result. Better results are obtained by adding pure casein to a ration composed of a mixture of 12 % of maize (63 % of the mixture) and beans (37 % of the mixture).

In a previous paper the authors showed that 6 % of milk proteins in a food mixture just suffice to support normal growth in rats. The protein mixture from 80 % maize and 20 % beans has, therefore, just about one-half the biological value for growth that the total protein mixture in milk possesses.

4) A detailed study was made of the exact nature of the mineral deficiencies of the maize and bean mixtures. The results confirm others previously obtained in which sodium and calcium were shown to be the elements determining the unsatisfactory character of the mineral content of seeds in general. This is of great importance in human nutrition and agricultural practice in districts where the drinking water is nearly free from lime and sodium chloride. Efficient utilisation of food by growing animals is not possible when the diet is deficient in these elements.

As regards human nutrition in districts where the water is low in calcium and sodium the ration may be completed by milk or leaves of plants. The use of leaves in almost strictly vegetarian diets maintains life, as they supply the mineral deficiencies and the shortage of the fat-soluble A in the seeds.

The investigations carried out by the authors by special methods, show how near the danger line is the faulty diet of some classes of people, even in the United States. GOLDBERGER (*Journal of the American Medical Association*, 1916, Vol. LXVI, p. 471) obtained experimental pellagra with a diet typical of that eaten by pellagrins — wheat flour (patent), corn meal, corn grits, corn starch, white polished rice, standard granulated sugar, cane sugar, sweet potatoes, pork fat (fried out of salt pork), cabbage, collards, turnip greens and coffee. Calculated on a wet basis, the sweet potatoes, cabbage and collards made  $\frac{1}{6}$  th. of the diet, but, on a dry basis, only 4 % of the total solids. This quantity is insufficient to make good the serious shortage of calcium and sodium in the remainder of the diet. Sodium is supplied by the salt added, but there is still a deficiency of calcium. The work of the authors shows that there is far from an adequate quantity of the fat-soluble A in GOLDBERGER's diet, the protein content of which was not above 8 % of the food mixture. In an experiment carried out by the authors a diet containing 12.5 % of protein, supplied by 63 % of maize kernel and 37 % of beans, was insufficient for rats. As the animals developed normally immediately casein was added to their diet, the deficiency of the diet can only be attributed to shortage of proteins. In the light of such experimental evidence it is entirely unnecessary to attribute the cause of pellagra to the absence of a hypothetical "vitamine".

3 - War Bread (Unsalted Lime Bread). — DUBOIS, RAPHAEL, in *Comptes Rendus des Séances de la Société de Biologie*, Vol. LXXX, No. 17, pp. 818-821, Paris, November, 1917

The French nation eats bread containing from 15 to 20 grms. of salt per kg. In Paris the proportion is sometimes as high as 22, and even 25 grms. Those eating 1 kg. of bread, therefore, consume an average of 20 grms. of salt in the bread alone. The amount of salt mixed with other foods may, on an average, be placed at 10 grms. Finally, according to GAUDIN (*Cours de Minéralogie*, 1st. Series, 2nd. Ed., pp. 65-66) the amount of salt contained *naturally* in the food eaten is not less than 20 grms. a day.

These facts show that, on an average, an adult person consumes 50 grms. of salt daily. The figure seems excessive, since the amount of salt excreted daily, without decomposition, is estimated at from 18 to 20 grms. only. This would mean that 30 grms. of salt remain to supply the hydrochloric acid of the gastric juice, which seems hardly admissible, even for hyperhydrochloric subjects. It is true that vegetarians require a larger quantity of salt, since, according to BUNGE, it helps to remove the potassium, contained in large quantities in vegetables, but, in proportion to people living on a mixed diet, there is but a small number of vegetarians.

An excess of salt in seasoning causes the assimilation of the food to be destroyed to too great an extent, and this can only be compensated for by an increased consumption. The author's experiments show that the amount of unsalted bread eaten is less by one quarter than that of salted bread. The same would probably apply to other foodstuffs, a very important fact from an economic point of view. Moreover, an excessive consumption of solid foods is accompanied by an excessive consumption of liquids, and, among those using alcoholic drinks, the salt becomes accessory to the alcohol.

In view of the great benefit derived in therapeutics by the *elimination of chlorides* in many cases of arthritis, it is probable that the *preventative* partial elimination of chlorides by the use of unsalted bread would be advantageous.

There is no danger that the insipid taste of unsalted bread would prevent its being eaten by the public. In certain countries, for example in some of the districts of Italy, Tuscany in particular, salt is not added to the bread. Many people prefer it to salted bread; others soon get accustomed to it.

The author recommends a bread which he calls *unsalted lime bread*, because, to every kg. of bread, are added from 15 to 20 grms. of calcium carbonate, which, unlike lime water, does not "kill the yeast" by preventing the dough from rising. Washed chalk or precipitated calcium carbonate answer the purpose equally well, but the author prefers prepared chalk. The chalk is mixed with water, and with it is made the dough, which gains in whiteness, rises perfectly, is never acid, and has a very appetising smell. The excess of calcium carbonate has no ill effects, as the author proved by eating large quantities of it.

The author does not believe the idea of adding chalk to bread to be new, but has been unable to find any published reference to it.

- 1 - **The Nutritive Value of the Soy Bean.** - DANIELS, AMY, L. and NICHOLLS, NELL, B., in *The Journal of Biological Chemistry*, Vol. XXXII, No. 1, pp. 91-102, 6 diagrams. Baltimore, October, 1917.

This paper gives an account of work carried out at the Department of Home Economics, University of Wisconsin, Madison. In order to determine the nutritive efficiency of a given food, it is necessary to make biological tests, as well as chemical determinations, for chemical analysis does not determine the optimum amounts of the various amino-acids necessary to physiological well-being nor the chemical nature of the food accessories.

In the biological experiment made by the writers, the soy bean was fed to rats. In a preliminary investigation, it was found that when these animals were given exclusively soy beans, they failed to grow. When, however, the rats were placed on a ration consisting of: soy beans (60 per cent.), lard (16 per cent.), maize starch (18.7 per cent.) and a salt mixture (6.3 per cent.), containing calcium, chlorine and sodium, the animals grew and reproduced, but the adult rats were under-sized, and the younger were not only smaller at birth, but the litters were also smaller. The addition of the salt mixture, therefore, did not produce a perfect food. The fact that 2 generations of rats were reared on this ration, shows that the soy bean must contain an abundance of MAC COLLUMS'S "fat-soluble A" which, on the contrary, is only present in small quantities in certain cereal seeds. This was also confirmed by the difference in the development of several rats fed upon a diet of purified food substances (freed from fat-soluble A) and the growth of four animals of the same litter which were fed a ration of 50 per cent. soy bean without any addition of fat. In this connection, it is interesting to note that Mac Collum found that the extracted oil of soy bean was quite free from "fat-soluble A".

Young animals produced and suckled by mothers having a liberal supply of "fat-soluble A" were able to withstand a shortage of this material during their most rapidly-growing period much better than those animals whose mothers received considerably less. A plausible explanation for this marked difference in the behaviour of the 2 groups seems to be, that a diet suitable for the maintenance of adult animals, and for reproduction, does not contain a sufficient amount of fat-soluble A to insure the growth of young animals. The writers conclude from these 2 facts: 1) animals can accumulate a reserve of fat-soluble A; 2) young animals require a greater amount of this substance than adult ones.

In all the experiments, the value of the protein of the soy bean has been demonstrated, and it appears to be quite equal to that of the casein of milk. These findings are somewhat surprising in view of the fact that the protein of other legumes (peas and white beans) has been found insufficient.

A diet lacking "water-soluble B" retards growth and produces abnormal physiological conditions such as beri-beri and polyneuritis.

In the dietary used in these experiments by the writers the soy bean was the only possible source of "water soluble B". Since none of the rats in this investigation presented any of these symptoms, it is logical to conclude that soy beans are rich in this water-soluble substance.

An economic consideration of the soy bean leads us to conclude that it is one of the most valuable of leguminous seeds for human consumption, for it contains a high percentage (36.5 per cent.) of physiologically good protein, a considerable amount of energy-yielding material in the form of fat (17.5 per cent.) and carbohydrate (12 per cent. digestible), and a large amount of "water soluble A" and "water-soluble B", which substances promote growth.

EXPERIMENTAL  
AND  
ANALYTICAL  
WORK.

5 - Recent Investigations and Observations Made at the Imperial Institute (London) (1). — *Bulletin of the Imperial Institute*, Vol. XV, No. 1, pp. 1-46; 78-82; 107-113. London, January-March, 1917.

THE PRODUCTION OF WHEAT AND OTHER CEREALS IN EGYPT. — More than  $\frac{4}{5}$  of the total area cultivated in Egypt (in round numbers 5 350 000 *jeddans*, or Egyptian acres = 5 553 300 English acres), is capable of growing wheat, but so long as cotton remains as remunerative a crop as it is at present, there is very little chance of an increase in the area at present assigned to wheat.

Indeed with the abnormally high prices which now rule for cotton, it is probable that the area occupied by that crop will exceed the percentage of 32.5, which has been the proportion of the cultivated land occupied by it during the last few years. The restriction of the cotton areas during 1915 and 1916 allowed a slight increase in the area sown in wheat and a few other cereal crops, but the increase must be looked upon as abnormal, and the extent usually given to that crop may be considered to be 1 300 000 *feddans* (1 349 400 acres) Taking the cultivated land roughly at 5 350 000 *feddans* (5 553 300 acres), this represents 24.3 per cent of the whole.

The most important cereals grown in Egypt in addition to wheat are maize, rice and millet (barley occupies 7-8 per cent. of the cultivated area, but it is almost entirely used for cattle food). As is shown by Table I, the country is unable to grow sufficient cereals for its own consumption (including the amount required for seed) in normal years. No new lands are likely to become available for wheat planting in the near future, but much remains to be done in improving the wheat strains, the methods of marketing, and the system of cultivation.

(1) See also, B. 1915, No. 5: R. 1917, No. 118. (Ed.)

Wheat is grown in Egypt entirely as a winter crop. Owing to the wheat harvest taking place in April-May, it cannot advantageously be followed by cotton; therefore the wheat land is left fallow until July-August, when maize may be planted, or until October or November, and then bersim (*Trifolium alexandrinum*) is sown.

FLAX-GROWING IN EGYPT. — In *Bulletin* No. 12, *Technical and Scientific Service, Ministry of Agriculture, Egypt*, an account is given of an experiment in flax-growing which has been conducted at the Government Farm at Guemmeiza with the object of determining the amount of seed which yields the best results with reference to both seed and fibre. The best fibre and the largest yield were obtained from the most thickly sown plots, but the amount of seed secured was smaller than in the less thickly sown plots. On some of the plots, the stalks were gathered before the seed had been completely formed, so as to obtain the best possible fibre, whilst sacrificing the seed-crop. Other plots were harvested at a later date, in order to obtain both fibre and seed, and a third series were left still longer with the object of obtaining a good crop of seed. The seed obtained from the 2<sup>nd</sup> and 3<sup>rd</sup> series of plots was found to contain approximately the same percentage of oil; this is in harmony with the results obtained in England by EYRE and FISHER (*Bulletin of the Imperial Institute*, 1916, Vol. XIV, p. 115). The supposition that good flax can only be obtained by harvesting the crop before the seed is ripe, was not supported by the results of this trial; the best return for the fibre crop per feddan was secured in the latest harvest.

A sample of flax straw produced in the course of these experiments was sent for examination to the Imperial Institute in 1917. It consisted of retted flax stems from 26 to 30 in. in length and from  $\frac{1}{16}$  to  $\frac{1}{8}$  in. in diameter; it yielded about 25 per cent. of soft, fairly lustrous fibre usually about 24 in. long; the strength was irregular. The extracted fibre was valued at £ 200 per ton in London in January 1917; in normal times it would be worth about £ 60 per ton.

COTTON CULTIVATION IN AUSTRALIA (1). — The climatic conditions of large areas in the warmer parts of Australia are well adapted for the growth of cotton. At the present time, however, it is cultivated to only a small extent in Queensland and the Northern Territory. The chief difficulty is the high cost of picking, as so far, no satisfactory cotton-picking machine has been found. It is thought that the labour difficulty might be overcome by growing the crop in small areas only, which could be picked by the family of the cultivator. The British Cotton Growing Association and the Government encourage the industry by different means, by: making a grant, providing seed for experiment and guaranteeing a minimum price, etc. Samples of cotton grown in Queensland, Western Australia and New South Wales have been received at the Imperial Institute in recent years. Their quality varied from mediocre to good; the samples from New South Wales were on the whole the most promising.

1) The water contained 0.75 % of alkali expressed as sodium carbonate.

A sample of the seed hairs of *Ipomœa albivenia* were also examined. Large quantities of this material can be collected in Natal and Zululand, where it is known as Kaffir, or Natal, cotton. It is, however, not a very promising material, for the fibres are weak, and therefore difficult to spin or card. It is much less resilient than kapok, and therefore not so useful for stuffing upholstery. These seed-hairs might be used in the production of nitro-cellulose, but they contain much less cellulose than cotton (77.3 as against 95 to 96.5 per cent.). The raw fibre would not be sufficiently absorbent for use in surgical swabs, though it is more absorbent than untreated cotton.

NEW PAPER-MAKING MATERIALS. — The following substances were recently investigated at the Imperial Institute as sources of pulp for paper-making: — cladodes of *Ecdiocolea monostachya* (fam. *Restiaceae*) from Western Australia; the wood of *Neoboutonia macrocalyx* (*Euphorbiaceae*) from the East Africa Protectorate; the bark of *Brachystegia Randii* (*Leguminosae*) from Rhodesia. The analyses of the substances are set forth in Table III. The first is of about the same value as Algerian esparto grass, the yield of pulp from the air-dry material being 44 per cent.; the second has good qualities and supplies from 46 to 50 per cent. according to treatment; the third yields from 32 to 35 per cent. of good pulp. It seems likely

that fibre of value for textile or cordage purposes could be prepared from *Brachystegia Randii* bark.

<i>Brachystegia Randii</i> . . . . .	11.8	3.4	43.0	—	1.27 — 2.54

SOME NEW OIL SEEDS FROM AMERICAN PALMS. — The oil seeds dealt with are: — the kernel of babassu and bassoba (*Attalea* sp., possibly *A. funifera*); tucan, or tucum, or large Panama nuts (*Astrocaryum* sp.); Paraguay kernels (*Acrocomia* sp.), which only differ from *A. sclerocarpa* in their smaller size. They contain respectively 4.2 - 6.5 - 6.0 per cent. of moisture, and yield 70.2 - 52.0 - 69.4 per cent. of fat in proportion to the dry matter.

The chemical characters of the oils and the composition of the palm kernel meal are given in Tables IV and V. These kernels seem to be a valuable addition to the oil seeds now utilised as sources of fat in the edible fat industry. The cakes made from them have a feeding value about equal to that of coco-nut cake.

the natives. The average weight of the fruit (drupe) is: entire fruit 7.6 gm., the nut, 5.0 gm. and the kernel 0.7 gm. The kernels contained 4.1 per cent. of moisture and yielded 57.2 per cent. of bright yellow liquid oil, equivalent to a yield of 59.6 per cent. from the dry kernels. This oil had the following characters: specific gravity at 55° C., 0.928; acid value, 1.9; saponification value, 191.5; iodine value 133.6 per cent. (it is therefore a semi-drying oil). It appears that this oil can be used for food. It is, however, very difficult to extract the kernels, owing to the softness of the latter, and the extreme hardness of the shells.

The pulpy mesocarp should have a moderate nutrient value, but trials would be necessary before it could be definitely recommended as a cattle feed. Its percentage composition is as follows: moisture 16.6; crude protein, 7.9, (of which 6.5 is true protein and 1.4 other nitrogenous substances); fat, 1.62; carbohydrates, etc. (by difference), 65.4; cellulose, 3.0; ash, 5.5; nutrient ratio 1:8.6; food units, 89.

THE PRODUCTION OF SANDALWOOD OIL IN MYSORE, BRITISH INDIA. — The source of true sandalwood oil is the heartwood of the trunk and larger roots of *Santalum album* Linn., a small evergreen tree native of South India, more particularly of Coorg and Mysore. It is estimated that about  $\frac{7}{10}$  of the world's supply of sandalwood is derived from Mysore, in which State it is a Government monopoly, the extraction and exploitation of the wood being entrusted to the Forest Department. Before the war, about 52 per cent. of the sandalwood oil exported from India was sent to Germany for distillation; about 18 per cent. to the United States, and from 10 to 20 per cent. to the United Kingdom. The value of the total export of sandalwood from India in 1913-1914 was £128 626. In the two years that preceded the outbreak of war, the price of sandalwood oil in Mysore had doubled, the Government having restricted the amount offered for sale to about 2 500 tons, the estimated amount of the world's annual consumption. This restriction of output was to some extent justified in view of the ravages of a

disease called the "spike", which in recent years has caused the destruction of a large number of trees. The spike disease first appeared in 1900; the method adopted for its control consists in uprooting affected trees and is said to have checked its spread.

On the outbreak of war, the Government started the distillation of sandalwood oil in Mysore for export to Europe. The first factory was erected near the Institute of Science, at Bangalore; it is now producing 5000 lb. a month. A second factory is now being erected in Mysore; it will ultimately have an output of about 20 000 lb. of oil per month, which will probably be sufficient to supply the whole of the European demand for this product. There is considerable demand for sandalwood in Eastern countries, where it is employed for perfumery and ceremonial uses, and also for carving.

Owing to the high price of true sandalwood oil, several substitutes have been placed on the market; of these the chief is the oil obtained from *Amyris balsamifera*, a Rutaceous plant native of Venezuela, and known commonly as West Indian sandalwood. The so-called sandalwood exported from Australia is mainly derived from *Fusanus spicatus*; in addition there is a small export of the South Australian sandalwood, *F. acuminatus*, or "quandong", which goes principally to China and India.

*Santalum album* is grown in Celebes (Dutch East Indies); it is said to be grown in Java, and has also been successfully cultivated in Mauritius. The tree is semi-parasitic; in India some 144 different trees have been recorded as serving as hosts, of which 26 are leguminous species. As *S. album* is of slow growth, it requires to stand from 20 to 40 years in order to develop the maximum amount of fragrant wood, therefore it is necessary to select as hosts, species of trees that have a life of at least 40 years. Probably trees of the leguminous family would be most suitable for the purpose, such trees as *Pongamia glabra* Vent., and *Albizzia Lebbeck* Benth. commonly serving as hosts in India. In the matter of soil, *Santalum alba* does not appear to be very exacting, but the highest yields of oil have been obtained from wood grown on poor rocky soils.

**SOUTH AFRICAN GUM.** — A sample of typical South African gum (probably derived from the "white thorn" *Acacia horrida*) had the following composition: moisture, 14.5 per cent.; Ash, 2.9 per cent.; matter insoluble in water, 2.0 per cent.; Acid number, 3.9; relative viscosity of a 10 per cent. solution at 22° C., 8.0. This sample yielded a mucilage possessing good adhesive properties.

**BURMESE BLACK VARNISH OR LACQUER.** — This is a natural varnish obtained by making incisions in the bark of the "black varnish tree" (*Melanorrhoea usitata*), one of the *Anacardiaceae*, which occurs in various parts of Burma, in Manipur and Siam. In 1914-1915, the different Forest Circles of Burma produced 3 390 cwts, of which the value was £ 1 138. A sample examined at the Imperial Institute contained: moisture, 5.3 per cent.; ash, 0.2 per cent.; matter insoluble in benzene, 2.6 per cent. It was found that the varnish required about 3 days to harden in an atmosphere saturated at a temperature of 30-35° C. The length of time that this

varnish takes to dry is a obstacle to its employment. Further, it is very similar to Chinese and Japanese varnish; the latter is derived from *Rhus vernicifera*.

**CHICORY SUBSTITUTE FROM SOUTH AFRICA.** — The inhabitants of certain parts of South Africa, notably the Waterberg and Zoutpansberg districts of the Transvaal, utilise the dried roots of the "witgatboon" (*Caparis albitrunca*) as a substitute for chicory. A firm of chicory manufacturers in London who were commissioned by the Imperial Institute to examine this product, stated that it was a very good substitute for chicory. In February 1917, the price of the root in South Africa was stated to be 20s. per 100 lb.

**TOBACCO FROM NORTHERN PROVINCES, NIGERIA.** — Tobacco is grown for native use in almost every part of the Northern Provinces, Nigeria. The crop is carefully cultivated and manured, but the method of curing it is primitive and the product quite unfit for export. In 1915, experiments were inaugurated by the Agricultural Department with the object of producing a "bright" tobacco of the Virginian type. Trials were started at Mairana and Ilorin Experiment Stations. The extreme dryness of the air at the former Station made it difficult to handle the crop successfully, but at Ilorin the results were distinctly promising. Four samples of tobacco produced at Ilorin (3 American varieties, Boyd, Yellow Prior, and Sterling, and one indigenous variety, Native) were examined in 1916 at the Imperial Institute, and found to be of good quality. The excess of nitrogen and nicotine which they contained is no doubt due to the recent and abundant use of nitrogenous fertilisers.

The results of chemical examination expressed on the material conditioned to contain 12 per cent. of moisture are shown in Table VI.

## CROPS AND CULTIVATION.

6 - On the Origin of "Terra Rossa" (Red Soil) in Italy (1). — GORTANI, M., in *Mondo sotterraneo*, Year IX, No. 6, pp. 125-131; summarised by TISSI, E. in the *Bollettino del R. Comitato Geologico d'Italia*, Vol. XLVI, Part 2-3, pp. 50-52. Rome, 1917.

SOIL PHYSICS,  
CHEMISTRY  
AND  
MICROBIOLOGY.

The discussion on the origin of "terra rossa" is considered chronologically in the above communication. Formerly considered as a product of muddy eruptions, terra rossa had ended by being considered as the insoluble ferruginous clay residue from the dissolution of calcareous rocks due to atmospheric agencies.

The difficulty of admitting that a small insoluble residue of calcareous rock should be remain in place while the waters dissolve and transport the tens and hundreds of feet of thickness of the same rock, induced VINASSA and WALTHER to revive the question some years ago and to admit that the formation of "terra rossa" was largely due to the precipitation of the colloidal ferric hydrate derived from the iron compounds contained in the calcareous rock dissolved by surface water.

In 1911, CHELUSSI studied a large number of samples of "terra rossa" from the Carso of Trieste, the districts of Siena (Tuscany) and Aquila (Abruzzi), and northern Sicily. He found the samples to be composed of ferriferous or aluminiferous granules united with accessory minerals not identical, in quantity or quality, to the minerals present in the insoluble residues of the neighbouring calcareous formations.

In 1912, TUCAN, after having carefully studied and analysed many "terre rosse" from the Croatian Carso, arrived at the unexpected conclusion that they are not essentially constituted by a ferriferous clay, as was previously thought, but by an aluminium hydrate (sporogelite predominating), with which are associated the ferric hydrate and other minerals present in the insoluble residue of the limestones.

In 1913, the author, considering the studies previously mentioned, arrived at the conclusion that "terra rossa" is the insoluble residue of limestones and dolomites, essentially constituted of hydrates of aluminium (sporogelite), nearly always combined with hydrates of iron and other minerals, both authigenous and allothigenous, and that the formation of this soil could, speaking generally, be explained by VINASSA's theory, modified in the sense that the precipitation of the colloidal aluminium hydrate is added or superposed to the precipitation of the colloidal ferric hydrate.

TUCAN does not accept these theories, but considers "terra rossa" (sporogelite and accessory minerals) as a primary formation already present in the limestone, and explains the presence of the insoluble residue by the sieve-like structure of the carsic rock being like a filter, owing to fractures and the slow action of atmospheric agencies. Change of the primitive

(1) See B., 1915, pp. 1133—1138. (Ed.).

deposit can, according to TUCAN, give rise to colloidal secondary formations of oxides of aluminium, iron and manganese.

GALDIERI strongly contests these various theories, and recalls that limestone, as laboratory experiments have shown, dissolves completely in carbonic acid, in which also dissolves the alumino-ferruginous residue resulting from dissolving limestones in dilute acetic and hydrochloric acids, acids which do not exist in a free state in nature.

While studying the limestones and "terre rosse" of southern Italy, GALDIERI found that the residue left after dissolving limestones in acetic or hydrochloric acid does not completely correspond to the residue from "terra rossa". He draws numerous deductions from this fact and proposes to replace previous theories by a new one.

According to GALDIERI, "terra rossa" is simply an aeolian deposit, and in support of such an interpretation he recalls :

- a) the unstratified nature of the deposits of "terra rossa" ;
- b) its predominance in semi-arid regions ;
- c) its presence on tablelands covered with vegetation (which are the places most liable to the accumulation of aeolian deposits ;
- d) its mineralogical and morphological constitution.

Further, the fact that "terra rossa" is usually found on pure limestone has been exaggerated, so GALDIERI thinks, on account of theoretical conceptions ; in any case, he explains it by the permanency of pure limestone and its great permeability. GALDIERI attributes the high iron-content of "terra rossa" to the fact that it is retained in the state of a colloidal hydrate because of the special physico-chemical conditions of both it and the medium. He is of the opinion that the presence of aluminium hydrate is due to a true process of laterisation carried out under warmer climatic conditions than the present ones.

The author remarks that, to be able to judge the value of GALDIERI's theory, it would be necessary to carry out long researches not only in those regions studied by the latter, but also in other regions where the deposits of "terra rossa" are on a larger scale.

Speaking broadly, the writer observes that GALDIERI's strong criticism of the fundamental idea generally admitted cannot be considered as final, but in any case, no matter what the fate of his hypothesis, it has certainly been the means of stimulating more close and searching attention to the questions concerning the origin of "terra rossa".

7 - **Adsorption by Soils.** — HARRIS, J. F., in *Phys. Chem.*, XXI, 454-473, 1917 ; abstracted in *Journal of the Society of Chemical Industry*, Vol XXXVI, No. 19, p. 1057. London, Oct. 15, 1917.

Experiments were undertaken to determine whether the acidity of those soils which redden litmus paper, but which give a neutral solution, is due to colloidal adsorption. Soil was placed in contact with dilute solutions of barium chloride for 24 hrs., with occasional shaking, and the barium in solution before and after the treatment determined. When the results were calculated according to the equation  $\frac{x}{m} = ac^{\frac{1}{n}}$  (1), representing the adsorption

isotherm, the values obtained for  $\frac{x}{m}$  were constant' showing that the action was one of adsorption and not of double decomposition. No chlorine was adsorbed from the barium chloride. Solutions containing other metallic ions were also used, and it was found that the number of equivalents absorbed was the same for ions of the same valency and increased with the valency, except in the case of potassium, which was adsorbed by soil in very high quantity. The potassium absorbed could be recovered by treatment with salt solutions, again in the order of the valency of the metal. When a soil was treated with a solution of two salts, the number of equivalents of each metallic ion adsorbed was less than with each salt separately, but the total number was greater.

**8 - Studies on the Organic Matter of the Soil of the United States.** — I. GORTNER, R. A. (Agricultural Experiment Station, University of Minnesota), Some Data on Humus, Humus Carbon and Humus Nitrogen, in *Soil Science*, Vol. II, No. 5, pp. 395-441, 16 fig., bibliographical index of 31 publications + II plates. New Brunswick, 1916. — II. IDEM, A Study of Carbon and Nitrogen in Seventeen Successive Extracts, with Some Observations on the Nature of the Black Pigment of the Soil. *Ibid.*, Vol. II, No. 6, pp. 539-548, 1 fig., bibliographical index of 5 publications, 1916. — III. IDEM, On the Production of Humus from Manures. *Ibid.*, Vol. III, No. 1, pp. 1-8, bibliographical index of 8 publications 1917. — IV. GORTNER, R. A. (Associate Bio-chemist) and SHAW, W. M. (Assistant in Soils Agricultural Experiment Station, University of Minnesota), Some Data on Humus — Phosphoric Acid. *Ibid.*, Vol. III, No. 2, pp. 99-111, bibliographical index of 24 publications, 1917. — V. MORROW, C. A. (Professor of Chemistry, Nebraska Wesleyan University) and GORTNER, R. A. (Associate Professor of Agricultural Bio-chemistry, University of Minnesota), A Study of the Nitrogen Distribution in Different Soil Types. *Ibid.*, Vol. III, No. 4, pp. 297-331, bibliographical index of 50 publications, 1917.

Since the time of LIEBIG, the nature of the organic matter of the soil has interested chemists, and every year sees extensive contributions to the voluminous literature upon this interesting subject. Mr. GORTNER has chiefly turned his attention to the solution of the following problems:

a) Is the humus, the ammonia, or alkaline hydroxide extract of soils a typical soil product, formed in the soil by the action of bacteria, or can similar extracts be obtained from unchanged vegetable material?

b) Does the humus, "the matière noire" of Grandeau, consist entirely of one or more black compounds, or does it contain in addition a greater or less proportion of colourless substances whose presence is masked by a black pigment?

c) Does a 4 per cent. sodium hydroxide solution extract the same substances and in the same proportion as a 4 per cent. ammonium hydroxide solution?

d) Is the soil nitrogen present in a form different from that in which the nitrogen occurs in plant materials, or does the nitrogen of the soil exhibit the same solubilities as vegetable nitrogen?

**I. — DATA RESPECTING HUMUS, ITS CARBON AND NITROGEN.** — The writer selected air-dried samples of: 8 mineral soils; 3 peats; 1 very acid

(1) FREUNDLICH equation:  $\frac{x}{m}$  being the concentration of the adsorbed substance in the adsorbent,  $c$  the equilibrium concentration of the solution;  $a$  and  $n$  are two coefficients variable with the temperature and the nature of the substances employed. (*Fd.*)

"muck" soil; 5 kinds of unaltered vegetable material and in these he estimated the :

- 1) total carbon and total nitrogen.
- 2) Carbon and "humus" soluble in 4 per cent. ammonia before and after leaching the samples in 1 per cent. hydrochloric acid.
- 3) Carbon and nitrogen soluble in 4 per cent. sodium hydroxide, both before and after leaching.
- 4) Carbon and nitrogen extracted by 4 per cent. sodium hydroxide from the *residue* remaining after the samples had been extracted with 4 per cent sodium hydroxide and then leached with hydrochloric acid.
- 5) Carbon and nitrogen extracted by water from the residue of extract 4.
- 6) Nitrogen soluble in 1 per cent hydrochloric acid.

The various solutions were also submitted to colourimetric determinations.

From the numerous analytic data he obtained, the writer concluded that :

1) The humus extract of mineral soils and peats is not a typical soil product, for very similar extracts can be obtained from unchanged vegetable materials.

2) "Humus", the "matière noire" of Grandeau, does not consist of one, or more, black compounds, but it also contains a large proportion of almost colourless substances, the presence of which is normally masked by the black colour. In fact, the humus extract of Sphagnum peat, of brown peat, or of unaltered vegetable material, has a red-brown colour which only appears black in concentrated solutions.

3) A 4 per cent. solution of sodium hydroxide does not extract either the same substances, nor the same quantity of substances as does a 4 per cent. solution of ammonium hydroxide. Thus, from a given soil, after leaching with 1 per cent. hydrochloric acid, ammonium hydroxide will extract *less carbon* and at the same time *more colour* than will a sodium hydroxide solution.

4) In general, the forms of soil nitrogen appear to be quite similar to those forms occurring in unchanged vegetable materials (sweet fern leaves, oak leaves, oat and lucerne plants) except that they are less soluble in 1 per cent. hydrochloric acid and in 4 per cent. sodium hydroxide.

5) All the mineral soils studied and one calcareous peat, contained a *very dark* soil *pigment* which is absent from the unchanged vegetable materials. This pigment appears to be the only substance which can, with certainty, be said to be a true soil product. It is suggested that perhaps it is of bacterial origin, but as it contains a relatively small proportion of nitrogen, it would appear to have but little importance, *per se*, in the problem of soil fertility.

6) Inasmuch as the "humus" extract of soils is undoubtedly a mixture of organic compounds, many of which are colourless, and in all probability are extracted from unchanged plant or animal materials, and inasmuch as the soil pigment present in this solution probably rarely exceeds 40 per cent. of the "humus", a determination of the "humus" as ordinarily carried out, appears to be wholly without scientific justification. It ap-

pears to be far preferable to determine the humus from the total organic carbon.

II. — A STUDY OF CARBON AND NITROGEN IN 17 SUCCESSIVE SOIL EXTRACTS. OBSERVATIONS ON THE NATURE OF THE BLACK PIGMENT OF THE SOIL. — With a view to isolating this pigment, the writer proceeded as follows :

A sample of silt loam was leached with 1 per cent. hydrochloric acid and then extracted 9 consecutive times with fresh portions of a 4 per cent. sodium hydroxide solution. A sample of the residual soil was removed in order to determine the carbon, nitrogen and humus present. The remainder was further extracted for 4 consecutive times with a 25 per cent. solution of sodium sulphate (to act on the flocculation of the clay), then twice consecutively with the same solution to which was added 15 per cent. sodium hydroxide solution. Part of the residue was used for the determination of the carbon and nitrogen ; the remainder was again leached with hydrochloric acid, and then extracted with 1 per cent sodium hydroxide solution. The extract obtained was divided into 2 portions: one for the determination of the carbon after the flocculation of the clay by potassium sulphate, the other for the determination of the humus after the flocculation of the clay by ammonium carbonate. The final residue was dried and used for the humus determination. The black pigment was separated by precipitation with sulphuric acid from the extracts obtained with sodium sulphate.

The writer arrived at the following conclusions :

1) The black soil pigment does not dissolve in 4 per cent. sodium hydroxide ; this agrees with the writer's earlier observation.

2) This pigment is soluble in very dilute sodium hydroxide solutions, but is at once precipitated if the amount of the sodium hydroxide is increased to 4 per cent.

3) This pigment is also precipitated by salts of the heavy metals. It forms a water-soluble compound with ammonia when an ammoniacal solution is evaporated to dryness. It is not dialysable.

4) Two attempts were made to prepare the soil pigment in a pure form, but the resulting products contained such a high content of ash (37.47 and 51.17) that the ultimate analysis was unreliable. The pigment with the least ash content gave : Carbon, 61.3 per cent. ; Oxygen, 31.6 per cent. ; Nitrogen 2.8 per cent. ; all calculated to an ash-free basis.

5) The first 6 extractions with sodium hydroxide removed relatively more nitrogen than carbon from the soil, but the remaining 3 sodium hydroxide extractions, as well as the 6 pigment solutions, contained relatively more carbon than nitrogen. The final soil residue had a ratio of carbon : nitrogen very much higher than that of the original soil.

III. — THE PRODUCTION OF HUMUS FROM MANURES. — In order to study this question, the writer carried out the following experiment :

Four earthenware jars, each provided with a hole in the base for drainage, were filled with a mixture of sub-soil and organic materials as follows :

*Jar 1* : — 7 500 gm. of moist sub-soil + 500 gm. of a mixture of silk waste and quartz, containing 4.50 per cent. nitrogen, indicating that about 140 gm. of protein had been added.

*Jar 2* : — 7 500 gm. of moist subsoil + 460 gm. of a mixture of  $\frac{1}{3}$  cleaned wool and  $\frac{2}{3}$  quartz flour, containing 4.53 per cent. of nitrogen.

*Jar 3* : — 7 500 gm. of moist subsoil + 50 gm. of powdered calcium carbonate + 300 gm. high grade "patent" flour.

Jar 4: — 7500 gm. of moist subsoil + 300 gm. alfalfa meal.

A sample was taken of each of these mixtures which was dried in the air, bottled, and set aside for analysis. The remaining soil was placed in the earthenware jars and moistened with water containing approximately 50 cc. of an almost clear suspension of soil bacteria. All of the jars were then planted with barley, but as poor growth was obtained in some of them, the vegetation test was soon discontinued, the barley stalks cut off, and the jars of soil allowed to remain in the greenhouse under fallow conditions, care being taken to keep the air moist.

At the end of one year, samples were taken from each jar representing depths of 0.3 inches and 4 to 6 inches; these samples were dried at 65° C., ground to pass a 1 mm. sieve and bottled for analysis. The remainder of the soil was left in the jar for further action by bacteria and fungi.

During the course of the experiment, some changes were observed in jars 1 and 2. A fortnight after the experiments were started, there appeared in the soil of jar 1, black streaks about 1 to 5 mm. below the surface. In jar 2, there was a layer of black soil 3 to 4 mm. thick, and about 5 mm. below the surface. Below these streaks or layers, the soil was again of its original colour. On the other hand, no noteworthy changes in coloration were to be observed in jars 3 and 4, even after the experiment had been started for one year, though after this period, purple spots appeared throughout the soil of jar 1 and a mould odour, as well as mould mycelia were easily observed. The soil of jar 2 was similar to that of jar 1 except that the spots were black. The soil from jars 3 and 4 had a mouldy odour, but no black or purple coloration, so that the presence of mould mycelia cannot be definitely taken as the causation of the black or purple colours.

The determinations of the organic carbon, nitrogen and humus made at the beginning and end of the experiment gave the following results:

1) In all the jars there was observed a decided loss of organic carbon, ranging from 18.4 to 55 per cent. of the carbon originally present.

2) There was likewise a loss of nitrogen, but this loss was not proportional to the loss of organic carbon, ranging from 5.0 to 26.5 per cent. of the nitrogen originally present.

3) There was a loss of humus soluble in 4 per cent. ammonia, and this loss was proportional to the loss of nitrogen. Whether, however, there is a causal relationship here can only be determined by more extended work.

4) As regards the humus extract by 4 per cent. ammonium from the unleached soil, no significant change was apparent in 3 of the jars, but in the 4th, there was a loss of 60 per cent.

5) These experiments furnish no evidence that an increase of soil "humus" is brought about by specific humification. On the contrary, all the evidence is directly opposed to such a conclusion, and it appears altogether probable that the maximum amount of ammonia soluble material is present in the soil immediately after a green manuring crop has been ploughed under, and before the "humifying" bacteria or fungi begin their work.

IV. — SOME DATA ON HUMUS PHOSPHORIC ACID. — The writers determined the phosphoric acid extracted from soils, peats and unchanged vegetable materials: a) by means of 1 per cent. hydrochloric acid; b) by 4 per cent. ammonia, after leaching with the above acid; c) by ammonia without leaching with hydrochloric acid.

The different extracts were evaporated to dryness and the burnt residue was used for analysis. The following conclusions have been reached:

1) Of the 8 mineral soils investigated, 7 yielded more phosphoric acid when extracted with 4 per cent. ammonia than when 1 per cent. hydrochloric acid was used; only in 1 soil did hydrochloric extract appreciably more phosphoric acid than did the ammonia.

2) There appears to be no relation between the amount of phosphoric acid ( $P_2O_5$ ) extracted by ammonia from the soil unleached with hydrochloric acid (HCl.) and that extracted after leaching.

3) The amounts of humus-phosphoric acid present in the 8 soils studied, when compared with the known fertility of these soil types do not support the theory that a high humus-phosphoric acid content is a necessary factor in soil fertility.

4) Probably the greater part of the phosphoric acid present in humus ash is inorganic in nature, being derived from the colloidal clay and from the phosphoric acid ( $P_2O_5$ ) adsorbed by the colloids present in the ammonia solution. No method of analysis has yet been proposed which will distinguish between such adsorbed phosphoric acid and organic phosphoric acid.

5) There is no relationship detectable between the total nitrogen content of the soil and the phosphoric acid ( $P_2O_5$ ) extracted by the different treatments.

6) The amount of "humus ash" (even when the extractions have been carried out under identical working conditions) is extremely variable, from 6.7 to 32.6 per cent. Such a wide divergence can only be accounted for by the presence of considerable amounts of clay, or adsorbed mineral materials.

7) The "humification" of vegetable materials in contact with a mineral soil for an entire year did not increase the humus-phosphoric acid over that contained in the original subsoil.

8) What has been said regarding the colloidal adsorption of phosphoric acid ( $P_2O_5$ ), applies with equal force to determinations of humus-potash, and it is most probable that organically-bound potash does not occur in the soil in appreciable amounts, but that this alkali is found everywhere in a mineral condition and adsorbed.

V. — NITROGEN DISTRIBUTION IN THE DIFFERENT SOIL TYPES. — In these investigations, the writers used the following substances:

a) Fibrin hydrolysed in the presence of an ignited mineral subsoil, in the presence of stannous chloride.

b) A calcareous black peat.

c) An acid sphagnum-covered peat, hydrolysed alone, in the presence of a mineral subsoil, and in the presence of stannous chloride.

d) Seven samples of mineral surface soil: 1 clay loam — 3 silt loams — 1 prairie-covered loess — 1 forest-covered loess.

e) An acid "muck" soil.

f) Extracts of sphagnum-covered peat soluble in: 1 per cent. hydrochloric acid; 4 per cent. sodium hydroxide and not precipitated by hydrochloric acid; 4 per cent. sodium hydroxide but precipitated by hydrochloric acid.

For the separation by hydrolysis, and the determination of the

different forms of nitrogen the writers used the VAN SLYKE method (1), modifying it a little, in order to obtain the following categories :

Total nitrogen.

Ammonia nitrogen.

Humin nitrogen (under the form of "humin") insoluble in soil.

Humin nitrogen, precipitated by calcium hydroxide.

Total humin nitrogen.

Basic nitrogen set free as ammonia by 50 per cent. potassium hydroxide.

Basic nitrogen not set free by this treatment.

Amino-nitrogen of bases.

Non-amino-nitrogen of bases.

Amino-nitrogen in filtrate from bases

Non-amino nitrogen on this filtrate.

Total nitrogen regained.

From the many results obtained, the writers conclude as follows :

1) The figures for the ammonia nitrogen in a protein analysis are not appreciably changed when the hydrolysis is carried out in the presence of the protein material.

2) The "humin" nitrogen is greatly increased by hydrolysis in the presence of ignited mineral soil. The histidine fraction entirely disappears.

3) The analysis of a pure protein in the presence of an ignited mineral soil does not give reliable results for the different fractions. Therefore the figures obtained for the nitrogen distribution in soils are of value only when used for purposes of comparison. Such data should not be compared with analyses of pure proteins.

4) Since practically all the mineral soils investigated give furfural on treatment with an acid, it is very likely that a considerable amount of the total humin nitrogen found is due to the presence of carbohydrates in the soil which give rise to furfural during hydrolysis. This may combine with certain of the nitrogen compounds of the soil and cause an increase in the humin nitrogen, as well as adsorb or occlude nitrogenous compounds in the "humin" formed from furfural by polymerisation.

5) Special attention should be given to a new fraction of nitrogen discovered in these investigations. This is a fraction removed from a colourless solution by the addition of calcium hydroxide (3.26 to 9.21 per cent. of the total nitrogen). It must consist almost entirely of non-protein substances, since the organic substances in this precipitate are colourless

and adsorbed by, or combined with, the metallic hydroxides (of calcium, aluminium, iron).

6) *True* humin nitrogen (22.93 to 28.27 per cent.) remains in the residual soil after hydrolysis, in company with non-humin nitrogenous compounds.

7) The strength and volume of the hydrochloric acid used in hydrolysis has little effect on the nitrogen distribution of the hydrolysate, provided acid as strong as constant-boiling acid is used, in the proportion of at least 2 parts of acid for 1 of soil. In this manner, the writers extracted on an average 72.19 per cent. of the total nitrogen, with a minimum of 66.63 per cent, and a maximum of 77.65 per cent. The average of the results obtained by other investigators in the case of 37 very different soils, appears to be 75.19 per cent of the total nitrogen.

8) On comparing different soils, it is seen that organic nitrogen dissolves during hydrolysis to almost the same extent, regardless of the origin and nature of the soil,

9) On comparing the different extracts from sphagnum-covered peat, very interesting results were obtained. The portion soluble in sodium hydroxide and *not* precipitated by hydrochloric acid, gave a nitrogen distribution approximating very closely that of a normal plant protein. On the other hand the nitrogen dissolving in the preliminary hydrochloric acid leaching showed a nitrogen distribution which is certainly not due exclusively to protein materials, *e. g.* an ammonia nitrogen percentage of 65.40 and amino-nitrogen in filtrate from bases, of 17.11 per cent.

10) The most significant fact brought out by this study is, that the nitrogen distribution is very *uniform* in *different* soil types. This is to be expected, seeing that the nitrogen distribution in soils is an *average* distribution of all the plant and animal nitrogenous products that find their way into the soil.

9 - Construction and Use of Farm Weirs for Measuring Small Streams of Irrigation Water, in U. S. A. — *United States Department of Agriculture, Farmers' Bulletin 831*, 18 pp., 5 fig., 7 tables, bibliographical index of 20 publications. Washington, June, 1917.

Irrigation is becoming more and more extensive in the arid west of the United States. In order to measure the water supplied by irrigation concerns, the author describes the construction of weirs for measuring comparatively small streams of flowing water.

The weirs described are: *a*) the rectangular; *b*) the CIPOLLETTI (trapezoidal); and *c*) the 90° triangular-notch types. The latter form deserves to be more widely used than at present for measuring small quantities of water.

The dimensions for constructing permanent or temporary weirs are given, as well as discharge tables calculated for various heights of water by the ordinary formulae.

The bulletin closes with a list of 20 publications of the U. S. Department of Agriculture relating to irrigation.

TILLAGE AND  
METHODS OF  
CULTIVATION

10 - **Electrocultural Experiments in Great Britain and France.** — I. BLACKMAN, V. H. and JÖRGENSEN, J. (Imperial College of Science and Technology), The Overhead Electrical Discharge and Crop Production, in *The Journal of the Board of Agriculture*, Vol. XXIV, No. 1, pp. 45-49, figs. 5 London, 1917. — II. JÖRGENSEN J., in *The Electrical Review*, pp. 452 and 454, October, 1916; pp. 497-501, November 1916, pp. 21-23, July, 1917, London. — III. ANGOT A., L'ETIT, H., SAGNIER, H., MANGIN, L. and SCHRIBAU, in *Comptes rendus des Seances de l'Academie d'Agriculture de France*, Vol. III, No. 37, pp. 1054-1062. Paris, 1917.

I. — The account of experiments carried out in 1916 at Lincluden Mains Farm, Dumfries, and continuing those of previous years (1). The object was to study the effect of the overhead electric discharge upon crop production, the experimental crop being oats.

*Description and Treatment of Selected Area.* — A large field of 9 acres, which had in the past given uniform crops, was selected; the soil was a sandy loam. It had been pastured without manure for the 3 previous years. One acre was chosen as the electrified area; the sides of the rectangular plot measured 88 by 55 yds. Two half-acre control plots were chosen at such a distance from the electrified plot as to receive practically no discharge. The difficulty of confining the discharge to the special area to be electrified was much reduced by keeping the wires low (2). The distance of the control plots, together with the low position of the discharge wires, made the use of the earthed screen of wire netting previously used to prevent the spread of the discharge to the control areas, unnecessary.

The overhead discharge was applied by means of a series of 21 wires running parallel to the sides of the rectangular special area. The wires were about  $4\frac{1}{2}$  yds. apart and supported at their ends at about 7 ft. above the ground (at the end of the experiment, the wires had sagged downwards to a height of only 6 ft.). One end of the wires was connected to the soil and the other to the secondary circuit of an induction coil, producing a potential of about 90 000 volts on the wires. Two ball interrupters, placed in the circuit, gave sparks some 6 inches long. A series of LODGE valves were introduced to reverse the current (3). The primary circuit of the induction coil received, through a rotary mercury interruptor, a 3-ampere current at 50 volts, as in preceding years, but the intensity of the discharges was much greater, the wires being so much closer together ( $13\frac{1}{2}$  ft. against

(1) See *The Journal of the Board of Agriculture*, April, 1910, p. 16; January, 1912, p. 862; October, 1913, p. 582; January, 1915, p. 944; and October, 1916, p. 671 (*Authors' note*). — For an account of the 1915 Experiments at Lincluden, see *R.*, 1916, No. 1260. (*Ed.*)

(2) JÖRGENSEN and PRESTLY have shown (*Journal of Agricultural Science*, Vol. VI, Part 3, pp. 337-548, 1914) that when the wires are fixed at a considerable height above the ground the wind may carry the discharge over a wide area. (*Authors' note*). — This article was summarised in *B.*, 1915, No. 17, under the title: *The Distribution of the Overhead Electrical Discharge Employed in Recent Agricultural Experiments.* (*Ed.*)

(3) See *The Electrical Review*, October and November, 1916, pp. 452, 454, 499-501.

14 ft. in 1915 and 19 ft. in 1914), as well as nearer the soil (7 ft. against 10 in 1915 and 14 in 1914) (1).

*Effect of the Discharge on the Crop.* — The oats were sown on March 27 and appeared above ground on April 13, the discharge being started on April 14. By May 16, there was a marked difference between the electrified and the control areas; the plants which had received the discharge were taller and of a deeper green colour than the others.

Measurements were taken at intervals of the average height of the plants of the three areas; the results are given in the following table:

Plots	18th. June	25th. June	3rd. July
Electrified . . . . .	19 in	24 in	32 in
Control I. . . . .	14 "	19 "	21 "
Control II . . . . .	12 "	18 "	20 "

Measurements were discontinued after July 3, it not being possible to get among the plants without damaging them. The effect of the discharge was clearly visible for some distance round the electrified area, or the height of the crop round the area was above the average, gradually diminishing with increasing distance.

The electrified crop was markedly taller than the rest of the field, as is well shown in 2 photographs, taken on August 8.

The discharge was continued until August 17, being used only in the daytime and discontinued during rain. It was applied for 848 hours altogether during the season.

Heavy rain storms set in during the latter part of August, causing considerable laying of the heavy electrified crop and delay in cutting. This led to failure to garner the whole crop, owing mainly to loss of grain before harvesting. The crop was cut on August 28 and 29, carted on September 11, and threshed on September 12. The yields in grain and straw are given below.

	Grain			Straw
	1st Quality	2nd. Quality	Total	
Electrified Area (1 acre) . .	1 942 lb.	695 lb.	2 637 lb.	4 924 lb.
Control Area I ( $\frac{1}{2}$ acre) . .	630 "	210 "	840 "	1 218 "
Control Area II ( $\frac{1}{2}$ acre) . .	714 "	210 "	924 "	1 401 "

The electrified area, as compared with the control areas, gave an increased yield in grain of 49 per cent., and in straw of 88 per cent. If the

(1) The intensity of the charge received may be increased by: a) lowering the wires; b) reducing the distance between the wires; c) reducing the thickness of the wires. The wire used was silicium bronze of gauge 24.  
(Authors' note)

weather had been more favourable, the yield of grain would have been greater. The 1915 results, also with oats, but with a weaker discharge, gave 30 per cent. increase in grain and 58 per cent. increase in straw.

*Financial Results.* — Taking current prices in the district at the end of September, 1916 (oats, first quality, 3s. 9d. per bush.; 2nd. quality 3s. 1d. per bush.; straw, £2 15s. per ton), the increased value of the crop works out (with bushels of 42 lb.) at £6 7s. per acre.

The net profit is rather difficult to estimate. The apparatus used to produce the high-tension current was inefficient, not being such as would be used for work on a large scale; for every 100 watts in the primary circuit only 10 or 12 watts were obtained from the secondary one. Thus, with an efficient apparatus, the same cost would have enabled discharges to be made over a much larger area.

In addition, current supply from a power station was not available, so the supply was obtained from a small dynamo driven by a petrol engine. The cost of the current used, about 130 B. of T. units, when calculated at 1d. per unit, only works out at 11s. The cost of a large-scale installation cannot be estimated at present, but the profit shown above would permit of a heavy expenditure on an installation.

*Residual Effect of Discharge.* — A new and important aspect of the problem has been disclosed by the discovery that the application of the discharge one year may increase the next year's crop. The field in which the experimental crop was grown in 1915 was sown with grass and clover at the same time. The difference between the crop of clover-hay produced in 1916 on the electrified area of 1915, and that on the non-electrified area, was very obvious, and there was a marked increase in the weight of the crop produced from the electrified area. Two photographs, taken on September 15, show the *second* crop of clover which had come up on the hay stubble; the first crop of clover hay had been cut in July, 1916. The difference in growth on the two areas was very marked. It should be noted that this field had been well limed before sowing the oats. This question of "after-effect" will be investigated in future experiments, as if the electric discharge may benefit a succeeding crop, its agricultural value will be greatly enhanced.

*Problems still needing Investigation.* — The writers conclude that the use of the overhead electric discharge is not sufficiently investigated as to warrant its practical adoption. The most suitable strength of discharge has yet to be ascertained, as well as the most economical methods of producing the necessary high tension current. There also remain the questions of the light, humidity of the air, nature of the soil, etc., to be studied.

II. — An account of other electro-cultural experiments carried out in various districts of England in 1916. The following are the principal results:

*Strawberries.* — The electric discharge produced an increase in yield of 80 % for young plants, and of 25 to 30 % for old plants.

*Potatoes.* — Increased yield of 20 to 50 % bearing, not on the number of tubers, but on their size.

*Carrots, Beets, Tomatoes.* — Increased yield of from 25 to 50 %.

*Leguminous Plants.* — The immediate effect of the discharge was somewhat harmful to these plants, which fix atmospheric nitrogen, whilst they benefited from the *after-effect* of the previous year's discharge, as was seen above for clover.

*The Electrical Review* for July 6, 1917, describes a portable outfit containing all the necessary apparatus for producing discharges over an area of from  $1\frac{1}{2}$  to  $2\frac{1}{2}$  acres. The maker offers to supervise the installation personally and supervise the working of the apparatus.

III. — At the meeting of the French Academy of Agriculture on November 28, 1917, M. ANGOT described Messrs. BLACKMAN and JÖRGENSEN's experiments, as well as other trials carried out in England. The communication was followed by a discussion, summarised below.

M. PETIT: The good effect of the electric discharge appears to be due to a greater *mobilisation* of the elements necessary to plant-life. If the leguminous plants only profited from it the second year, it is because they derive no benefit from the nitrification of nitrogenous manures during the first year; in fact, they suffer from excess of nitrogen. In continuing these experiments attention should be paid to this danger: in using the soil, good results might be obtained at first, but negative results might be obtained after some years' time.

M. ANGOT: The authors of the Lincluden experiments make all necessary reserves themselves. It is not the soil that is electrified, for the wires are 7 feet above the ground; the discharges act directly on the plants.

M. H. SAGNIER: The question of the agricultural use of electricity is not new to France. Several sets of experiments have been made concerning the action of electricity on plants. Thus, GRANDEAU carried out experiments in a metallic cage; a professor of the Agricultural Institute at Beauvais invented a system similar to a lightning-conductor and which gave results varying from good to mediocre.

M. L. MANGIN: Many attempts have been made in France to utilise atmospheric electricity; but it has but a feeble influence, and its use is limited, while in the experiment in Great Britain powerful currents were used, obtained by induction coils, which is very different, especially in the intensity of the action on the plants.

M. SCHRIBAUX has made thousands of experiments with large metallic cages; he found no marked difference between plants growing in the cages and those growing outside; the differences found seem due rather to experimental errors, and atmospheric electricity does not seem to have produced any noteworthy effect on the Gramineae experimented with. The poor results obtained in previous attempts were probably due to the agriculturist's lack of electrical knowledge and the physicist's lack of agricultural knowledge. The two experts should combine their efforts.

Finally, M. ANGOT considers that previous experiments cannot be compared with those made recently in Great Britain. In using atmospheric electricity only a feeble potential is obtained; the current only increases

by 30 or 40 volts per yard of elevation; when the wires are placed from 12 to 16 ft. above the soil, less than 150 to 200 volts are obtained. On the other hand, industrial currents producing up to 90 000 volts were used in the trials in Great Britain, so no comparison whatever can be made between the two procedures. Plants sheltered under a cage are simply submitted to the action of atmospheric electricity, which also influences the plants outside the cages, but the difference is very small. At a few inches from the ground, the difference of potential between air and soil does not exceed a few dozen volts; this would explain the contradictory results obtained by M. SCHRIBAUX.

11 - The Cultural Methods Applied to Winter Wheat in the Great Plains Area, U. S. A. — CHILCOTT, F. C., COLE, JOHN S. and KUSKA, J. B., in *United States Department of Agriculture, Bulletin* No. 595, 36 pp. 19 tables. Washington, October 11, 1917.

The Office of Dry Land Agriculture of the U. S. Department of Agriculture began field work in the investigation of methods of crop production in the Great Plains area in 1906. In 1916, 24 Agricultural Stations were occupied with experiments in crop production.

The bulletin analysed compares the returns obtained with different methods of cultivating winter wheat, using for the purpose the results of 75 annual cultural experiments carried out on 1137 plots by 13 Stations (1) which had made cultural experiments for a period of at least 4 years.

The area covered by these investigations consists of about 400 000 square miles of territory. It includes the western portions of North Dakota, South Dakota, Nebraska, Kansas, Oklahoma, and Texas, and the eastern portions of Montana, Wyoming, Colorado and New Mexico. These experiments supplied a large number of details which are summarised in the bulletin, so as to give only the most general and most important results.

After examining the results of the experiments of the 13 Stations, each of which is considered separately, the writers came to the following conclusions :

None of the cultural methods investigated, when applied to winter wheat, can overcome extremely unfavourable climatic conditions. It is only in the case of rainfall deficit, that the cultural methods under investigation have shown important effects upon yields.

Reducing the cost of production has, in most cases, proved a more important factor in determining profits, than increasing the yields by cultural methods.

The average difference in yields between early (deep : 8 inches), and late (shallow : 4 inches), ploughing is 1 bushel per acre. At most Stations, the difference is small, while at others the advantage of one over the other depends on the season.

The preparation of the ground after harvest : furrowing with a lister, and levelling the ridges preparatory to seeding, have resulted in an average increase of 0.9 bushel per acre over early ploughing and 2.2 bushels per

(1) See R. April, 1917, No. 328. (*Ed.*)

acre over late ploughing. As it is a cheaper method of preparation than ploughing, it has consequently been more profitable.

Subsoiling has increased the yields over ploughing without subsoiling at 5 Stations out of the 10 at which it has been studied. In the other Stations, this method has been the least remunerative.

Disked maize ground has given consistently high yields. This, together with the low cost of preparation, has resulted in this method showing the highest net returns of any of the methods at all the 11 stations where it has been tried, except at Huntley and Amarillo.

Summer tillage has given the highest average yields of any method under trial. However, on account of its high cost, due to extra labour and alternate-year cropping, it has not netted the highest returns, except at Huntley.

Green manuring is the most expensive method under investigation. It has given the smallest net returns of any of the methods at all the stations, except Huntley, where the profit from it is slightly greater than from either autumn ploughing or subsoiling.

12 - Method of Rice-Growing in Uncultivated Rice-Fields, in Italy. — See No. 37 of this Review.

13 - Improved Method of Sugar Cane Cultivation, in Salvador. — See No. 46 of this Review.

14 - The International Trade in Fertilisers and Chemical Products Employed in Agriculture (Half-Yearly Review) (1). — *Bulletin of Agricultural and Commercial Statistics*, Year VII, No. 9, p. 731-786. International Institute of Agriculture, Bureau of Statistics, Rome, September, 1917.

MANURES  
AND MANURING

This Review comprises nearly sixty pages, with a great number of data, either official or from trustworthy authorities. Separate headings are devoted to each of the principal fertilisers (*phosphatic, potassic and nitrogenous*) and chemical products employed in agriculture. The more important data are given below.

#### I. - The world's production.

NATURAL PHOSPHATES. — The production of natural phosphates in the United States, after having undergone some decrease in 1914, was in 1915 only about one-half of that of 1913 but recovered somewhat in 1916. According to data supplied by producers, the aggregate of natural phosphates sold in the United States in 1916 was 2 014 196 tons, against 1 865 123 tons in 1915.

Florida has produced 47 843 tons of rock phosphate, and 1 492 327 tons of pebble. The small extent of production of the first mentioned will be noticed, having declined since 1915, from a total of nearly 500 000 tons in 1913.

The figures from South Carolina, continuously on the decline, afford only 53 898 tons, less than half the production in 1913.

The production of Tennessee and Arkansas for 1916 is 369 951 tons of brown rock phosphate and 48 447 tons of blue grey phosphate, making a total of 418 398 tons.

This total includes a small quantity of brown rock phosphate from Kentucky and shews a decided increase on the figures of 1915.

(1) See R. January, 1917, No. 13. (Ed.)

In the western states only Utah and Wyoming contribute to the production of rock phosphate, as Idaho has now ceased to produce. The quantity from those two States was 1 730 tons in 1916, less than half that produced in 1915.

Makers of fertilisers claim that the price of phosphatic fertilisers should show a much greater increase than that of the rough phosphate, and that the rise is required in order to meet the enhanced price of the sulphuric acid required in the preparation of fertilisers. It is anticipated that the improvement in the manufactured quantities of natural phosphates, manifest in 1916, will continue during 1917.

The production of Egypt in 1916, amounting to 125 008 tons, shows a decided advance on that of 1915, and this also applies to Tunis. On the other hand the data from the Dutch West Indies and the French settlements in Oceania indicate a marked decline.

The subjoined table contains the principal numerical data recently to hand with regard to this subject. These data appear in the review published by the International Institute of Agriculture in Rome.

Natural phosphates	1916	1915	1914	1913

(a) Shipments. — (b) Shipments of the first nine months.

**BASIC SLAG.** — It is an exceedingly difficult matter to prepare an international table with regard to basic slag, in present circumstances. The production of Germany in the first ten months of 1916 was 1 592 thousands of tons, as compared with 2 500 in 1913. Production of this commodity has also decreased considerably in all other countries.

**SUPERPHOSPHATE OF LIME.** — The International Institute of Agriculture has published the following summary:

**POTASH SALTS.** — The German distribution department for production of potash has fixed the following aggregate for the year 1917:

Germany . . .	762 250 tons of pure potash
Other countries	155 200       "       "
Total . . .	<u>918 450</u> "       "

The deliveries of German potash salts in 1916 reached a total of 883 696 tons of pure potash, against 680 005 tons in 1915, 903 988 in 1914, and 1 110 370 tons in 1913. The considerable increase in the production of 1916 as compared with that of 1915 is explained by the fact that the requirements of German farmers have been better distributed over the whole year, and were consequently more uniformly met.

The production of potash salts in the United States in 1916 was estimated at 32 422 metric tons of products with an average of about 7 % of potash,

representing a production of potash amounting to 8818 tons. This is very nearly ten times the production of 1915, but no more than one-twentieth of the normal consumption of potash in the United States.

**NITRATE OF SODA.** — The production of the Chilean nitrate beds in the first half of 1917, was very nearly equal to that of the corresponding period in 1916; being 1 482 122 metric tons in 1917 and 1 488 792 in 1916. In fact after an interval of a year and a half a production analogous to that of peace times has again been attained. In the first half of 1915 a minimum was established on a production of about 600 000 tons. The stocks on 30 June have never been so large as as those of this year, on the Chilean coast.

They amounted to 936 235 tons, while they were 919 102 tons at the same date in 1916, about 850 000 tons in 1915 and 775 000 tons in 1914. In previous years the figures were still more moderate. The reason for this abnormal increase of stocks must be sought in the fact that, while production totals shew little change, the shipments to European and American markets have been much hampered by the lack of tonnage and by the consequent enhancement of freight rates. These shipments represent during the first half of 1917 a total of 1 230 947 tons against 1 356 629 tons in 1916, say 125 082 tons less in 1917.

These figures are however much larger than those of the first half year of 1915 which only reached 834 376 tons.

**SULPHATE OF AMMONIA.** — A production of 700 000 tons of sulphate of ammonia was expected in Germany for 1916, while, according to the most recent available data, the quantity for 1915, was 549 000 tons.

Owing to the enormous demand for steel, both for European countries and for American foundries, and the fact of the production of ammonia being based on the metal requirements, the production of sulphate in the United States has greatly increased since 1914.

In 1916 this production of ammonia, reckoned in sulphate, was about 294 838 metric tons, or 47.7 % more than in 1915. The increase is still clearer when the data are compared with those of 1914, when the production was only 166.016 tons.

For 1917 the American production of ammonia is estimated at 400 000 tons, reckoned in sulphate; and the capacity for production in 1918 may reach at least 500 000 tons.

The Japanese production of sulphate of ammonia is also continuously increasing. While in 1914 it scarcely exceeded 16 000 tons, it reached 31 824 in 1915 and in 1916 the total became 28 203 tons. For 1917 the estimate is 50 802 tons, and some people predict a total of 60 000 tons. This increased production is due to the same causes that have influenced the output in America.

The subjoined table summarises the information published by the Institute of Agriculture with respect to production of sulphate of ammonia from 1913 to 1916.

Sulphate of ammonia	1916	1915	1914	1913
	thousands of metric tons			
Spain . . . .	18	16	16	15
France . . . .	25	42	—	74
Great Britain .	445	433	433	439
Netherlands .	4	5	5	7
Russia . . . .	33	16	17	14
United States .	295	227	166	177
Japan . . . .	38	32	16	8
Australia . . .	7	7	6	5

**CYANAMIDE OF CALCIUM.** — Although some authorities estimate the German production of cyanamide in 1915 and 1916 at an aggregate of 600 000 metric tons, others do not reckon it at more than 400 000. We have adopted the

figure of 500 000 tons thus indicated as this appears to us not far from the reality. The American consular reports consider that, besides this production of cyanamide, Germany will recover in 1917 nearly 500 000 tons of ammonia, by the aid of the Haber process, which represents, for that country alone, a total of nitrates extracted from the atmosphere, equal to 200 000 tons. If to this are added the 140 000 tons of nitrates represented by the 700 000 tons of sulphate of ammonia expected in 1917 for that country, we find for Germany an available aggregate of 340 000 tons of nitrate, if we estimate the production of cyanamide in 1917 as equal to those of 1916 and 1915.

There is nothing official in connection with these figures.

Nor is there any other country which provides official data as to the present production of cyanamide, and this may be readily understood, since the whole, or very nearly the whole, of the nitrogenous products of this class are reserved for war work. In the subjoined table we have embodied the estimate as to capacity for production of cyanamide that are made by experts in this question and published by the Institute of Agriculture.

Cyanamide of calcium	1916	1915	1914	1913
	thousands of metric tons			
Germany . . . . .	500	500	36	24
Austria-Hungary . . . . .	24	24	24	7
France . . . . .	100	80	7	7
Italy . . . . .	20	25	16	15
Norway . . . . .	220	25	15	22
Sweden . . . . .		16	18	18
Switzerland . . . . .	29	12	7	7
Canada . . . . .	64	64	64	48
United States . . . . .				
Japan . . . . .	24	24	7	7
World's total . . . . .	981	770	193	155

**SULPHUR.** — The Italian production of raw sulphur during the first half of 1917 is officially estimated at 100 240 metric tons, against 269 374 and 558 107 tons respectively for the complete years 1916 and 1915.

Almost the whole of the sulphur produced in the United States at present comes from deposits in Louisiana and Texas, but deposits that have been, or might be productive, are known in Wyoming, Nevada, Utah, California, Colorado, Oregon and Alaska.

The production of 1915 and 1916 has not been officially estimated. Some authorities on the question reckon that the United States have consumed about 900 000 tons of sulphur, as compared with 300 000 tons in 1913. It is expected that the demand in the States will attain 1 200 000 tons in 1917, and may probably grow to 1,600,000 tons in 1918 if the war continues.

The subjoined table contains the numerical data of import tance taken from the summary made with regard to this product by the Institute of Agriculture:

Sulphur	1916	1915	1914	1913
	thousands of metric tons			
Spain . . . . .	11	10	8	7
Italy . . . . .	269	358	378	386
United States . . . . .	—	(a) 381	381	317
Japan . . . . .	93	61	60	49
Other countries (b) . . . . .	50	50	50	50

(a) Louisiana only. — (b) In round numbers.

**SULPHATE OF COPPER.** — Subjoined are the items of information published by the Institute:

Sulphate of copper	1916	1915	1914	1913
		thousands of metric tons		
Spain . . . . .	8	1	0	0
France . . . . .	27	16	21	26

United States . . . . .	(a) 6	19	14	25

(a) Production of the *American Smelting and Refining Company* only.

## II — International trade.

Owing to the prolongation of the war the extent of international trade in the products under review is considerably diminishing, with the exceptions of exports of nitrate of soda from Chili, and of occasional business in other articles. This reduction is consequent on the scarcity of tonnage and on the resulting very high freights, together with the restrictions and prohibitions of export imposed by the Governments, owing to the more or less important use of these products in manufacture of munitions.

As regards the United States, the nitrate trade continues very active, whilst for European destinations there is a decided tendency towards decrease.

## III. -- Wholesale prices.

Prices for fertilisers have on the whole continued to advance during the first eight months of 1917 and for some products the rise has been quite as pronounced as in the same period of 1916. The enhancement in sulphur has been quite a considerable one.

Quotations on the more important markets for the chief products have been as follows:

	Average of 1916	Average of January 1917	Average of July 1917	Average of the first half of 1917
	in gold francs per quintal			
<i>Chlorate of potash:</i>

- 18 — **Awards for the Location of Workable Phosphatic Deposits, in Germany.** — I. Bereitstellung von Fundprämien für abbauwürdige Phosphatlager, in *Kunstdünger- Futtermittel- Leim- und Oel- und Fett-Zeitung*, Year 11, No. 16, p. 109. Berlin, 1917. — II. Bereitstellung von Fundprämien für abbauwürdige Phosphatlager, Veröffentlichungen des Preussischen Landwirtschaftsministeriums. *Ibid.*, No. 9, p. 127.

The phosphatic manure requirements of German agriculture were satisfied in peace times chiefly by superphosphates prepared with imported phosphates and by basic slag. The production of the latter has diminished a little during the war, and the imported phosphates can only be replaced in part by those from northern France and Belgium and by the re-opening of the Lahn (Nassau) mines (1), carried out by the War Society for Phosphates.

By the use of new methods it is now possible to work phosphatic rocks which previously were not utilisable for the production of fertilisers. Nevertheless, in order to maintain German agricultural production at a normal level, a larger quantity of phosphatic manure is required. In order to obtain this, awards to the amount of 100 000 *Mark* (1 *Mark* = 11  $\frac{3}{4}$  *d. at par*) have been offered for the location of new phosphate deposits and for their study, either within the German Empire or in the occupied territories in the east. The funds for these awards have been supplied by the Prussian State, the German Agricultural Society, the Union of Manufacturers of Chemical Manures, and the "Rhenania" (Aachen) Factory of Chemical Products. All information with regard to new deposits must be addressed to the Prussian Department of Agriculture, Office for Raw Materials. If the deposits are worked the informant will receive a bonus per ton of mineral extracted.

19 - **The Collection of Kelp in the United States for Potash Production.** — *American Machinist*, Vol. 47, No. 14, pp. 599-600, figs. 2. London, November 17, 1917.

Various companies are now gathering kelp for potash production, along the Pacific coast from Los Angeles to San Diego.

The potash produced costs more than that imported before the war from Germany. It remains to be seen whether the cost of production can be sufficiently reduced.

The foliage of the kelp floating on the surface of the water is gathered as it contains most potash. Large barges are used, one end being fitted with a conveyor equipped with knives like those of mowing machines. These knives vary from 10 to 16 ft. in length, and are of triangular shape. The conveyors are sometimes fitted with side knives to clear the kelp completely and make it easier for it to be moved by the conveyor. These knives, as well as the conveyors, are run by chain from a small gasoline engine in the barge.

The conveyor is lowered into the water to the desired depth, usually about 4 to 6 feet. Below this the kelp contains less potash, and it is also more difficult to handle. The barges are usually towed, though some are motor driven. The power required is very small as they only move at the rate of about 2 miles an hour. The barges cost about \$65 000 each and vary greatly in capacity; some can gather 60 tons an hour while others only handle 300 tons in 24 hours. In calm weather the kelp is gathered at a distance of 2 or 3 miles from shore. About 3 crops a year are gathered.

The kelp contains about seven-eighths water and 21 to 22 tons of wet kelp give 1 ton of ash. The ash yields about 32 % of potash, or about 4 % of the weight of the wet kelp.

20 - **20 % Potassium Salt as a Fertiliser.** — VAN STORK, D. (Rijkslandbouwproefstation te Maastricht), in *Verslagen van Landbouwkundige Onderzoekingen der Rijkslandbouwproefstations*, No. XX, pp. 35-12. The Hague, 1917.

Since 1910 the 40 % potassium salt for fertilisers, largely used in Holland, was imported from Germany.

After the war the importation was reduced to limited quantities of a 20 % salt. The analysis of typical samples of this product showed the 20 % salt, like the 40 % one, to be composed chiefly of potassium and sodium chloride with, for example, as much as 50 % of carnalite (double chloride of potassium and magnesium), or large quantities of kieserite (magnesium sulphate).

21 - **The Effect of Different Methods of Inoculation on the Yield and Protein Content of Alfalfa and Sweet Clover.** — ARNY, A. C. and TATCHEK, R. W., in the *Journal of the American Society of Agronomy*, Vol. 7, p. 172-185; Vol. 9, p. 127-137. Washington, 1915, and 1917.

The experiments described were carried out during the season 1914 and 1915 in order to study the effect of different methods of inoculation on the yield and chemical composition of alfalfa and sweet clover, during consecutive seasons in three different plots.

The data collected refer to: — 1) the weight and protein content of three successive cuttings, during each of the two years, on 14 plots of in-

oculated alfalfa and 9 uninoculated control plots ; 2) the weight and protein content of one year's harvest on 2 plots of inoculated sweet clover, and 3 uninoculated plots ; 3) analyses of the aerial parts and roots of 2 consecutive alfalfa harvests and 2 consecutive sweet clover harvests on 3 inoculated and uninoculated plots of 1 square yard respectively.

The results show that, in the experimental plots, inoculation at the time the grain is forming causes a marked increase, at the first harvest, in the unit yields in dry matter and in protein content as compared with the results obtained on the uninoculated plots. During the following season (2nd. harvest), the differences are less marked, and disappear almost completely the following year owing to the rapid propagation of the bacteria inoculated on the uninoculated plots.

The inoculation of either alfalfa or sweet clover with soil from plots on which both had done well had a similar effect ; and, from an experimental point of view, better results were obtained with the inoculated soil than with the commercial cultures used. Liming with 5 ½ bushels of crushed lime per acre during the formation of the grain slightly increased the effects of inoculation.

Amongst these effects was also considered that of giving the plants a greater capacity for utilising the mineral fertilising elements of the soil, in so far as an increased harvest causes a greater loss of potash, phosphoric acid and lime from the soil. Another effect of inoculation is that the plants inoculated can form a slightly larger quantity of dry matter with a given quantity of mineral fertilising elements.

- 22 - *Isopyrum fumarioides*, A New Hydrocyanic Acid-Containing Plant. — MIRANDE, MARCEL, in *Comptes rendus des Séances de l'Académie des Sciences*, Vol. CLXV, No. 21, pp. 717-718. Paris, November 19, 1917.

In *Isopyrum fumarioides* L., a native of Siberia, grown in the Lantaret Alpine Garden, was found a substance which, under the influence of an enzyme, acting in a similar way to emulsine, and also contained in the plant, decomposes giving, among other products, hydrocyanic acid. An estimation by the method of FORDOS and GELIS, in the month of August, showed 100 gm. of fresh plants in full flower and even almost in fruit, to contain 0.249 gm. of hydrocyanic acid. This result places the plants among those most rich in cyanic products.

In a previous note (*Comptes rendus de la Société de Biologie*, November 22, 1913), the author drew attention to the presence of hydrocyanic acid in *Isopyrum thalictrifolius* L., which contained 0.042 gm. per 100 gm. of fresh plant.

- 23 - The Influence of Aeration of the Nutrient Solution in Water Culture Experiments, Remarks on the Water Culture Method. — STILES, W. and JØRGENSEN, J., in *New Phytologist*, Vol. XVI, Nos. 8-9, pp. 181-197, bibliography of 11 works. London, Oct.-Nov., 1917.

The writers emphasize the complexity of problems of water cultures, and endeavour to illustrate it especially in relation to aeration, having obtained similar results of those of HALL, BRENCHELEY and UNDERWOOD in

relation to the increase in growth of barley resulting from aeration (1); on the other hand with buckwheat a result was obtained similar to that of FREE, who found no benefit to result from aeration. It does not follow, however, that the same result would be obtained under all conditions of experiment. It is very likely that there are conditions in which aeration would produce no effect on the rate of growth of barley, or which would increase the rate of growth of buckwheat. The writers show also how different conditions bring about different increases in the rate of growth as a result of aeration.

There is at present no explanation why, under the conditions of the reported experiments, aeration should increase the rate of growth of some species and not of others; whether it is to be correlated with oxygen supply, removal of carbon dioxide, removal of diffusion gradients, or change in solubility conditions or other causes. There seems no doubt, however, that water culture conditions react in a different manner on different species.

It must be emphasized that a great deal of work must be done on the physical chemistry of water culture solutions before work can be done with necessary definiteness. Particularly investigation must be extended on dynamical principles as is clearly indicated from the investigations of PANTANELLI (2).

Further it is obviously desirable to work towards getting some more explicit principle which will take into account the co-operation of the various activities of the plant. It seems clear that at present neither the law of the minimum nor the principle of limiting factors as employed by BLACKMAN in regard to the sub-aerial part of the plant are expressions of our present knowledge of the life of the plant as a whole.

The detachment between plant physiology and agriculture might be removed if a working principle in regard to the physiological relations of plant processes were evolved which embodied the activities of both sub-aerial and subterranean parts of the plant. This is highly desirable, but it must be admitted that it seems remote at present.

24 — **Researches on the Pigmentation of the Ear of Wheat, in Russia.** — ЛЕВИЦКИЙ Ст., (LEVITZKI, St.), in *Журнал по опытной Агрономии* (*Review of Experimental Agronomy*), Vol. XVIII, Part 1, pp. 46-61. Petrograd, 1917.

There are 2 pigments which produce the colour of the glumes and other parts of the ear, namely, carotine producing *red*, and another pigment, of unknown composition, producing *black*. Ears wholly lacking pigment are of a clear straw colour and are described as *white*.

In south east Russia, *white* wheats give better yields, as regards quantity and quality, than the black or red wheats. This fact is thus explained by the writer: in dry climates the leaves dry and die even before maturity is attained, and the function of assimilation, already reduced, is then carried on by the glumes and other green parts of the plant. Now, the red or black pigment, which develops by displacing and replacing the chloro-

(1) See *B. Jan.* 1914, No. 12. (Ed.). (2) PANTANELLI, E., Über Ionenaufnahme. *Jahrbuch f. wiss. Botanik* (Pfeffer-Festschrift), pp. 689-733, 1915. (Author)

phyl granules, causes a still further decrease in assimilation, which results in incomplete development of the caryopses. This fact has led the plant-breeders at the Besen agricultural experiment Station to confine their attention solely to these wheats with *white* ears.

In order to study this interesting phenomenon and to ascertain the conditions, favourable or otherwise, for the accumulation of pigment in the tissues of Gramineae, the writer carried out a series of pot-culture and field experiments, using the following wheats: —

SOFT WHEATS. — 2 pure lines with *red* ears: *Triticum ferrugineum* and *T. militurum*; 2 pure lines with *white* ears: *T. erythrospermum* and *T. lutescens*.

HARD WHEATS. — 1 type with *red* ears: *T. hordeiforme*; 2 types with *black* ears: *T. coarulescens* and *T. abyssinicum*.

It was to be expected that the presence of pigment, by limiting assimilation, would retard the various phases of development and prolong the whole vegetative period. This was actually observed, as is shown by the phenological data given in the following Table:

*Phenological data regarding the various types of wheat employed.*

Types		Sowing	Sprouting	Beginning of earing	Full earing	Beginning of flowering	In full flower	Harvest
Soft wheats:								
Reds	<i>erythrospermum</i> . . .	14 IV	20 IV	8 VI	10 VI	11 VI	15 VI	25 VII
	<i>lutescens</i> . . . . .	<i>id.</i>	<i>id.</i>	7 VI	10 VI	11 VI	12 VI	<i>id.</i>
	<i>ferrugineum</i> . . .	<i>id.</i>	<i>id.</i>	9 VI	12 VI	15 VI	15 IV	<i>id.</i>
	<i>militurum</i> . . . .	<i>id.</i>	<i>id.</i>	10 VI	12 VI	15 VI	17 VI	<i>id.</i>
Hard wheats:								
Blacks	Red: <i>hordeiforme</i> . .	<i>id.</i>	21 IV	8 VI	11 VI	16 VI	18 VI	1 VIII
	<i>coarulescens</i> . . .	<i>id.</i>	<i>id.</i>	9 VI	12 VI	16 VI	18 VI	1 VIII
	<i>abyssinicum</i> . . .	<i>id.</i>	<i>id.</i>	3 VI	7 VI	9 VI	11 VI	19 VII

Although a damp and even rainy season had considerably hastened the development of all the varieties, including the pigmented ones, the characteristic differences between the different types of wheat remained, however, well marked. Compared with the *white* eared wheats, the beardless *red* wheat eared 3 days and flowered 4 days later; the *red* bearded wheats were 1 and 4 days later respectively. These data, obtained by field experiments, were confirmed by the results of pot-culture experiments.

As regards the quantity and quality of the grain harvested, the two series of experiments, both field and pot-culture, showed the superiority of the *white* wheats over the *red* and *black* types.

Those plants and ears, or parts of ears, that faced south-west, pigmented more quickly than plants or ears with a different orientation. Thus the phenomenon of pigmentation seems closely connected with the light, and,

in fact, the duration and intensity of the insolation is at its maximum when the sun is to the south-west. This explanation is confirmed by the results of pot-culture experiments with screens protecting the plants from the sun's rays. These results may be thus summarised :

- 1) The longer the plants are shaded, the less intense is the pigmentation.
- 2) The effect of the screen is more marked if the plants are shaded before flowering ; after that, the effect of the screen (negative effect) is more and more attenuated as the plants approach maturity.
- 3) The effect noticeable on the glume is repeated with the caryopsis, especially with the type *T. abyssinicum* which, when subjected to prolonged shading, finally loses the violet tint characteristic of its seeds.

**25 - The Viability of the Seeds of *Raphanus sativus* L. as Affected by High Temperatures and Water Content** (1). — WAGGONER, H. D., in the *American Journal of Botany*, Vol. IV, No. 5, pp. 299-313, 1 fig., bibliographical index. Lancaster, Pa., May, 1917.

The results of a series of experiments undertaken for the purpose of determining the definite relation between the water content of seeds exposed to high temperatures and their viability. Seeds of 3 varieties of radish (Icicle, Black Spanish Winter, and Crystal Forcing) were used, with an initial water content of from 4 to 71 per cent. In order to heat the seeds, the writer used 3 different methods: 1) in water ; 2) in 300 cc. Florence flasks placed in a wire cage and submerged in a water-bath ; 3) in an oven. Length of exposure, 30 minutes ; temperature, from 50° to 125° C. The seeds were then germinated on plaster of Paris blocks kept in a dark room at about 23° C. (100 seeds were used for each test). For one fortnight, the number of seeds that had germinated every day was observed.

The general resistance to high temperatures of the 3 varieties studied is very similar, therefore it is sufficient to give the data for Icicle (see Table II). An examination of the tables shows that there is a definite relation between the initial water content of seeds and their resistance. Seeds of an initial water content of 71 per cent., 50 per cent. and 45 per cent., are killed off at 60° C. The germinating capacity of the seeds increases with the decrease in the water content and the death point of the sample is raised. As the water content is decreased from 45 to 30 per cent., the lethal temperature shifts from 60° C to 65° C. Air-dried seeds give normal germination after treating at 75° C. and are killed between 95° C. and 100° C. Samples dried until only 4 per cent. of water is present, give a normal germination at 100° C., and are killed between 123° C. and 125° C.

In the check, the maximum daily per cent. of germination (45 per cent.) occurred on the 2nd. day, while of the treated seeds, those which had been exposed to temperatures below the critical temperature, gave highest percentages on the 3rd., or 4th. day (see Table II). The retardation becomes greater as the injury due to the treatment becomes more marked.

In determining the lethal temperatures for seeds of similar kinds, previous investigators had obtained very different results. This is probably

(1) On the subject of the effect of high temperatures on the vitality of seeds, see also R. June, 1917, No. 533 and R. September 1917, No. 891. (Ed)

due to the fact that, in these experiments, no attention was paid to the initial water content which, as has just been shown, causes the lethal temperature to vary within very large limits. The data obtained by the investigator depended upon the method used for heating the seeds. With an initial water content of 19 per cent., the lethal temperature was 65° C. for seeds heated in water; 85° C. for those heated in flasks; 105° C. for the seeds heated in the oven (See Table III).

Seeds heated in water absorb, during the experiment, a considerable amount of moisture, as is shown by the increase in weight. Seeds heated in flasks lose in weight for the first 10 minutes, after which the weight remains constant; seeds heated in the oven lose weight throughout the duration of the experiment, and it is owing to this loss of water, that they acquire greater powers of resisting the effect of high temperatures.

27 — **Reversible Transformability of Allelomorphs in Rice in Japan.** — TERA0, H. (Imperial Agricultural Experiment Station, Tokyo, Japan), in *The American Naturalist*, Vol. II, No. 611, pp. 690-698, VII Tables. New York, 1917.

PLANT  
BREEDING

In certain pedigree cultures of the rice plant, at the above-mentioned Station, the writer observed in 1912, families containing a number of sterile plants besides ordinary fertile plants. The former may be divided into 3 groups:

- 1) Forms yielding no seed.
- 2) Forms yielding a small number of seeds.
- 3) Mosaic forms with higher fertility.

These anomalies occurred in 2 families, A and B, which were derived from 2 plants each belonging to a different variety of rice. Tables I and II summarise the observations made on these families in 1912 and 1913.

From these observations it would appear that sterility, S, behaves as a simple recessive to fertility, F, which is a dominant. F and S form a pair of allelomorphs, and the seeds produced, by partial fertility, by the sterile plants, give rise to families composed of fertile and sterile individuals in the Mendelian ratio 3:1.

TABLE I. — *The Segregating Families A and B, in 1912.*

Family	Partial fertility of sterile plants								
	Number of fertile plants	Number of sterile plants	Total number of plants	Percentage of sterile plants	Ratio 3 : 1		Total number of spikelets	Fertile spikelets	
					Fertile individual- dominants	Sterile individual- recessives		Number	Percentage
A . . . . .	36	13	49	26.53 %	2.94	1.06	9 000	2	0.02 %
B . . . . .	105	25	130	19.23 %	3.23	0.77	14 941	434	2.90 %

TABLE II. — *The Families Derived from the Families A and B in 1913.*1) *The Progeny of the Fertile Plants.*

Families in 1912	Number of families in 1913			Ratio 1:2		Composition of partially fertile families in 1913			
	Com- posed of uniformly fertile plants	Compos- ed of fertile plants and of sterile plants	Total	Uni- formly fertile plants	Partially fertile plants	Number of fertile plants	Number of sterile plants	Total number of plants	Percentage of sterile plants
A . . . . .	10	22	32	0.94	2.06	1,068	346	1,414	24.46 %
B . . . . .	41	64	105	1.17	1.83	4,874	1,301	6,175	21.06 %

2) *The Progeny of the seeds on the sterile plants.*

Families in 1912	Number of families in 1913	Composition of families in 1913			
		Number of fertile plants	Number of sterile plants	Total number of plants	Percentage of sterile plants
A . . . . .	2	2	0	2	0.00 %
B . . . . .	24	401	115	516	22.29 %

In family A, which shows an exceedingly slight fertility (0.02 per cent.) of sterile plants, the segregation ratio in the offspring derived from fertile individuals, in 1913, is quite close to expectation. On the other hand, in family B, which shows a considerably higher grade of partial fecundity of sterile plants (2.90 per cent.), the progeny of the fertile (dominant) individuals exhibit considerable deviations from the expected segregation ratio, the fertile plants being more numerous.

The writer explains this phenomenon as follows: the dominant and recessive types concerned are assumed to be transformed by certain unknown causes into the other allelomorph. In the cases observed by the writer, the recessive allelomorph S, which appeared in 1912 in families A and B may have originated in the preceding generation (1911) by the transformation of the dominant allelomorph, F. This recessive state, however, of the hereditary substance has a tendency to revert to the original dominant state, and this reversion is especially likely to occur in the vegetative cells. Consequently, in recessive homozygotes, SS, the reversion will generally produce heterozygotic cells FS or SF, capable of being changed into homozygotic dominants FF. The heterozygotic cells thus formed will give rise to partial fertility in otherwise sterile plants, and cause the excess in the proportion of dominant individuals in plants arising from the seeds produced by the partial fertility of the sterile plants of family B. Finally, it may be assumed that, between families A and B, there exists a difference in the reverting tendency of the recessive and dominant characters; this tendency would be strongest

in family *B*, where the number of sterile plants in the process of segregation is, on an average, 4 per cent. less than was theoretically expected.

There are also cases where the transformation of the allelomorphs takes place in the reverse direction: from dominants to recessives. Thus, in the descendants of families which had proved to be constantly fertile, the occurrence of partially sterile families was observed. On the other hand, a constant tendency of the dominant allelomorph to be transformed into the recessive allelomorph was observed in certain strains; thus, in 1913, in certain partially sterile families there was a particularly high excess of recessive individuals.

The fertile spikelets of sterile plants are generally scattered at random over the panicle, and each fertile spikelet may be regarded as representing a separate case of reversion. In mosaic forms, which show higher fertility and are of rare occurrence, the reversion may have taken place in earlier stages of plant development, affecting more or less extensive groups of cells which gave rise to the fertile portions, such as groups of spikelets, half a panicle, or even a whole panicle, each group, however, constituting a single case of reversion. Consequently, when the count of fertile spikelets is made with only the first type of sterile plants, a more correct value for the frequency of reversion may be obtained. The result of such a count on 902 panicles containing 93 635 spikelets is 1858 fertile spikelets *i. e.* 1.98 per cent. of the total number of spikelets.

CONCLUSIONS. — The allelomorphs concerned in this investigation are probably subject to reversible transformations, of which the direction and frequency may be practically constant in a certain strain, but may be different in different strains.

As regards the conception of dominance and recessiveness, BATESON'S theory of "presence and absence of factors" is sometimes understood in the sense that the dominant allelomorph is regarded as due to the real presence of an hereditary material unit which is absent in the recessive allelomorph. Such a conception is not in full accordance with the idea of the reversible transformability of allelomorphs as described in this investigation.

This reversible transformability of allelomorphs is better explained by supposing that the dominant and recessive allelomorphs represent 2 alternative conditions, or phases, of a single hereditary substance somewhat resembling the chemical conception of polymerization.

28 — **Selection of Sorghum in Queensland, Australia.** — BROOKS, G. B., in *Queensland Agricultural Journal*, Vol. VIII, Pt. 4, pp. 194-197 + 1 plate. Brisbane, October, 1917.

Many varieties of both fodder and grain sorghums are cultivated in Queensland as they are well suited to this country on account of their resistance to drought.

Results are given of selection experiments designed to increase the grain yield, results which exceeded all expectation. Thus, for the fodder varieties, the grain production rose from 25.6 bushels per acre in 1916 to 52 bushels in 1917, and, for the grain varieties, from 50.8 bushels to 70.2

bushels. The average weights of the ears of the different varieties for 1916 and 1917 are given in the appended table :

*Weight of the ears of the different varieties of sorghum in 1916 and 1917.*

Variety	1916	1917	Heaviest head in 1917 selection
	Oz.	Oz.	Oz.
Crossbred, No. 1 Selection . . . . .	7.0	11.8	13.0
» No. 2 Selection . . . . .	—	10.0	10.5
Giant Honduras . . . . .	—	6.8	8.5
Cream Milo . . . . .	4.8	5.9	7.5
Feterita (Sudan Dhoura) . . . . .	4.0	5.6	6.8
Planters' Friend . . . . .	3.0	5.1	6.8
Standard Milo . . . . .	4.2	4.9	5.5
B. H. Kaffir . . . . .	3.4	4.7	6.8
Dwarf Milo . . . . .	4.2	4.9	5.0
Shantung Dwarf . . . . .	3.2	3.6	4.0
Saccharatum . . . . .	2.5	2.9	4.3
Amber . . . . .	1.2	1.8	2.0

The crossbreds show an absolute superiority in the weight of the ear, which gives good promise for the final results of the selection work. Certain undesirable characters, such as astringent grain and late maturing, will be eliminated later by suitable crossings.

It should be noted that the open seed varieties are less liable to attack from the maize caterpillar than the compact headed ones.

29 - **Researches on the 35 Factors Determining the Various Characters of the Genus *Pisum*, in the United States.**—WHITE, ORLAND E. (Curator of Plant Breeding, Brooklyn Botanic Garden), in the *Journal of Agricultural Research*, Vol. XI, No. 4, pp. 166-190, IV + 27 tables, bibliographical index of 39 publications. Washington, 1917.

Experimental researches on the genetic factors of *Pisum* carried out by a method of rigorous investigation at the Brooklyn Botanic Garden, New York, and completed by a critical examination of the works and experiments of previous writers.

The article in question is divided into 4 parts :

- I. — An analytic list of the 35 factors hitherto isolated and studied.
- II. — The effect of external agents upon the expression of these factors.
- III. — Factors which are transmitted independently of one another.
- IV. — Linkage of factors.

I. — **GENETIC OR DETERMINING FACTORS.** — There are 35 genetic factors which suffice to explain all the specific differences between the numerous species and varieties of the genus *Pisum*. These factors influence their : habit of growth ; time of flowering ; colour of stems, leaves and flowers ; colour of the cotyledons and of the seed-coats ; colour and character of the pods and seeds.

1) *Mode of growth* : T = tall, robust plants, large number of internodes ; (Le) = long internodes ; (Fa) = axillary flowers, round stems, regular

phyllotaxy; (Fn) = 1 or 2 flowers per peduncle; (Tl) = leaves with tendrils; (Lf) = late flowering; (Ef) = early flowering.

2) *Colour of flowers*: — A = salmon-pink or rose (B gives purple colour when combined with A).

3) *Colour of stem and leaves*: — The factors C and D give red colour to leaf axil and stem (with the addition of A) and a purple colour with the addition of B; the factor O produces green foliage, stems and pods; (Bl) coupled with W gives a glaucous tint.

4) *Colour of cotyledons*: — G, green cotyledon pigment, is made paler by presence of I.

5) *Colour of seed-coats*: (Gc) [A] produces yellowish green to greyish-brown seed coat, which colour is brightened or inhibited by H and becomes dark-brown in the presence of I; U = dark self-coloured seed coat; (Pl) = black-eyed pattern; E (A), with F and B, gives purple dottings which, in the absence of B, gives reddish dots; W = brown or maple mottling; N = violet eyes.

6) *Colour of pods*: — P<sub>1</sub> + P<sub>2</sub> gives purple pods; (Gp) = green.

7) *Seed characters*: — R produces smooth round seeds with simple, oval starch grains, low water content and excellent powers of germination under unfavourable weather conditions; L<sub>1</sub> (A) + L<sub>2</sub> give indent peas; S produces pods with separate, or free seeds.

8) *Pod characters*: — (Bt) = pods with blunt apex; P + V gives parchmented, smooth pods, which are not edible.

II — MODIFICATION OF THE EXPRESSION OF PISUM FACTORS BY EXTERNAL AGENTS. — The absence of (Fa) brings about intense fasciation of the stems, but this may be produced, even in the presence of (Fa), by damp weather and lack of sufficient sunlight.

Peas may be classified into 3 general types as regards height.

(1) dwarfs, with from 8 to 15 short internodes;

(2) half-dwarfs, with 10 to 18 long internodes, or 20 to 30 short ones;

(3) tall, with 35 to 60 well-developed internodes.

These differences depend upon 2 factors (Le) and T, and they are often modified by disease and high temperature, etc., which produce cases of dwarfs, even in the presence of the 2 factors (Le) and T.

The expression of the factor O may be suppressed by lack of sufficient salts (especially potash) in the soil. In this case, the aerial parts are of a sickly yellow colour.

Prolonged damp or rainy weather, even in the presence of the 2 factors A and B, change the purple colour to pink, or in extreme cases, to white.

The anthocyanin pigment of the seed-coat pattern, brought about by the factors E and F, is soluble in water and may be washed out in rainy weather, even in the presence of E and F.

Under greenhouse conditions, where the temperature and humidity are constant, the above-mentioned fluctuations do not occur, which allows of the different genetic factors being more distinctly individualised. Once the presence of a certain factor has been determined in a given pure line,

the absence or hindrance of the expression of this factor may be attributed to external agents.

III. — THE NUMBER OF INDEPENDENT FACTORS. — The cytological studies hitherto made show that there are 7 pairs of chromosomes in the species of *Pisum* investigated. According to the chromosome theory each determinant is localised at a single fixed point of a chromosome which is always the same.

Therefore, in the case of the genus *Pisum*, the number of characters, or groups of characters, which are wholly independent of one another, in the processes of separation and recombination, cannot exceed 7.

The writer carefully analyses the  $F_2$  ratios from crosses involving the presence and absence of 8 factors: — A; B; (Fa); I; (Le); G; R; (Ti), 2 of which [R and (Ti)] are linked, that is to say, localised in the same chromosome. Each factor has been tested out in crosses involving *all its possible combinations* with the other 6. Data involving many thousand  $F_2$  generation progeny, indicate that the number of independent factors is 7, namely: A; B; (Fa); I; (Le); G; R.

IV. — LINKAGE IN PISUM. — Two or more factors contained in the same chromosome are naturally united in such a manner that one character is always associated with the other corresponding character.

The writer has collected data concerning the following linked groups:

- 1) (Bf) S = pods with seeds separate or free; glaucous foliage stems and pods with "bloom".
- 2) A (Lf) = Salmon - pink or rose - coloured flowers; late flowering.
- 3) GO = Green cotyledons; green (non-glaucous) stems, leaves and pods.
- 4) A C E (Gc) Lr = in this group, the factors are so closely associated, that they may be considered as the expression of one single factor A.

In the genus *Pisum* the length of the chromosomes facilitates the phenomenon of crossing-over (I) and renders still more difficult the determination of independent characters, and of groups of characters based on the chromosome theory.

The writer has, however, been able to overcome this difficulty by means of multiplying the control experiments, so that the data obtained do not only permit of the determination of the gametic formula of any species, variety, or kind, of *Pisum*, but also make it possible to predict the results of any crossing.

(1) MORGAN and his collaborators have studied the interesting phenomenon of the reciprocal exchange of elements between 2 chromosomes, which phenomenon is called "crossing-over". Each chromosome may be regarded as the sum of a large number of linear segments, each of which would represent a genetic factor. If, for instance, in the case of 2 chromosomes of equal length and composed of an equal number of segments, these segments on touching one other should be exchanged, the phenomenon of "crossing over" would be produced and occur the more frequently the longer the chromosome and the less completely the elements of a series are united. Cf MULLER II, the Mechanism of Crossing-Over, in *The American Naturalist*, Vol 50, No 592, pp 193-221, 5 figs.; No. 593, pp. 284-305, 4 figs.; No. 594, pp. 350-366; No. 595, pp. 421-434, 4 figs. Lancaster, Pa., 1916. (Ed.)

30 - **The Indirect Effects of Certain Selections in Breeding Indian Corn.** — RIETZ, H. L. (Professor of Mathematical Statistics and Statistician) and SMITH L. H. (Chief in Plant Breeding, Illinois Agricultural Experiment Station), in the *Journal of Agricultural Research*, Vol. XI, No. 4, pp. 105-146, 5 Tables, 24 Diagrams, Washington, 1917..

As the result of individual selection experiments extending over a considerable period, the Illinois Agricultural Experiment Station has succeeded in creating from the same stock, 4 strains of maize which differ in their protein and oil content.

- 1) Maize with high protein content ("high-protein strain")
- 2) Maize with low protein content ("low-protein strain")
- 3) Maize rich in oil ("high-oil strain")
- 4) Maize poor in oil ("low-oil strain")

The article analysed gives the results of a statistico-experimental study undertaken in order to determine if chemical selection has indirect effects of an anatomical nature, or in other words, if the 4 above-mentioned strains differ, not only in chemical composition, but also in other constant biometrical values. The physical characters treated of are: 1) length of ears; 2) circumference of ears; 3) weight of ears; 4) number of rows of kernels on ears. The physical characters determined in 1905 (see Table 1), allow of real specific differences being established, but the observations of one year are not sufficient, for it may only be a question of fluctuations, that is to say, of differences and ratios that are not fixed and constant, but which vary from one year to another. To avoid this difficulty, the writers continued their work of selection, determination and classification for 11 successive generations of maize (1905-1915). The following is a summary of the most important results which they obtained.

**LENGTH OF EAR.** — In 1905, the length of ear was significantly different in the 4 strains. The smallest difference that existed was  $0.27 \pm 0.056$ ; this is about 5 times the probable error. We have to do here, therefore, with a well-defined character which persisted throughout the observation period in spite of different conditions of soil and climate.

**CIRCUMFERENCE OF THE EAR.** — The strains differed from one another to a greater extent and more constantly in the circumference of the ears than in the length. The types rich in protein had, as a rule, the most slender ears, while thicker ears were found in the strains which had a low oil content. The difference between the low-oil and the low-protein strains, although slight, remained constant throughout the period of observation.

**WEIGHT OF EARS.** — As in the two preceding cases, the high-protein and the high-oil strains had lighter (*i. e.*, shorter and more slender) ears than the low-protein or low-oil. This difference remained constant during the whole period of observation.

**NUMBER OF ROWS OF KERNELS ON EAR.** — In 1915 there was a significant difference in the number of rows of kernels on the ears; this difference remained constant during the succeeding generations. As this character is determined by inherent tendencies, and is less susceptible to external or environmental influence than the other characters considered, we should expect smaller fluctuations.

TABLE I — *Biometric Values obtained in 1905.*

Types of maize	Mean length of ear; inches	Mean circumference of ear; inches	Mean weight of ear; ounces	Mean number of rows of kernels on ear
High-protein . . . . .	$7.21 \pm 0.04$	$5.71 \pm 0.01$	$7.53 \pm 0.04$	$13.72 \pm 0.03$
Low-protein . . . . .	$7.80 \pm 0.04$	$6.51 \pm 0.02$	$9.66 \pm 0.10$	$14.71 \pm 0.06$
High-oil . . . . .	$6.87 \pm 0.04$	$6.05 \pm 0.01$	$7.79 \pm 0.07$	$15.65 \pm 0.06$
Low oil . . . . .	$7.48 \pm 0.04$	$6.65 \pm 0.02$	$9.84 \pm 0.05$	$12.80 \pm 0.05$

CONCLUSIONS. — The selection of chemical characters influences certain anatomical characters and leads to a progressive differentiation in length of ear; circumference of ear; mean weight of ear; number of rows of kernels per ear.

These two last characters present, in the case of the 4 strains studied, values and differences which remain constant even when the climatic and soil conditions vary.

There is an interesting correlation between the dimensions and weight of the ear on the one hand, and the height of the insertion of the ear on the stalk, on the other. There are 2 distinct cases :

1) In plants with 2 ears, the upper ear was, on an average, larger and heavier than the lower one. In 1909 the values given in Table II were found.

TABLE II. — *Biometric Values in Plants with 2 Ears in 1909.*

	Mean length of ear; inches	Mean circumference of ear; inches	Mean weight of ear; ounces	Number of rows of kernels per ear
Upper ear . . . . .	$8.325 \pm 0.062$	$5.970 \pm 0.028$	$7.69 \pm 0.12$	$16.76 \pm 0.16$
Lower ear . . . . .	$6.512 \pm 0.097$	$5.373 \pm 0.036$	$4.51 \pm 0.14$	$16.32 \pm 0.18$

These differences remained constant throughout the whole period of observation.

2) In plants with a single ear, low-ear strains and high-ear strains were

TABLE III. — *Biometric Values in Plants with One Row of Ears in 1908.*

	Mean length of ear; inches	Mean circumference of ear; inches	Mean weight of ear; ounces	Number of rows of kernels per ear
High-ear plants . . . . .	$6.380 \pm 0.039$	$6.148 \pm 0.018$	$6.980 \pm 0.080$	$18.09 \pm 0.091$
Low-ear „ . . . . .	$6.700 \pm 0.035$	$6.540 \pm 0.020$	$7.795 \pm 0.080$	$18.96 \pm 0.088$

to be distinguished. The ears of the first were, as a rule, longer, thicker and heavier than those of the second, and also bore more rows of kernels. In 1908 the values given in Table III were obtained.

The differences observed in 1908 remained constant for 6 consecutive years.

31 — **"Quality", a New Variety of Strawberry.** — ANTHONY, R. D., in the *Journal of Heredity*, Vol. VIII, No. 11, p. 509. Washington, November, 1917.

From the cross of the Johnson Late Strawberry with Sharpless made in 1889-90 by HUNN, about 400 hybrids were obtained. Of these, only one seemed of value and was named after its originator. In 1898, the Hunn variety, pollinated by Atlantic, gave many hybrids, of which only one survived and was called "Quality". In 1907, seedlings of this plant were obtained by self-pollination. Two of these were retained for a study of sex, one of which was perfect (with both stamens and pistils), the other imperfect (with pistils only). The perfect plant was self-pollinated and gave seedlings lacking in vigour, of low yield and with small berries. The imperfect plant, pollinated by the perfect one, gave large, very vigorous and extremely productive plants with fruit above the average in size. By propagating this variety a very valuable commercial type might be obtained.

34 — **Results of the Enquiry of the Office of Agricultural Information of the French Ministry of Agriculture on Manitoba Wheat (1).** — *Feuille d'informations du Ministère de l'Agriculture*, Year 22, No. 45, p. 10. Paris, Novembre 6, 1917.

CEREAL  
AND PULSE  
CROPS

The Manitoba wheat distributed in the spring of 1917 among the different departments was grown under very varying conditions. The results of the enquiry made by the Office of Agricultural Information lead to the following conclusions:

**Soil.** — Manitoba wheat does well in all wheat soils, that is to say, medium loams, calcareous loams and rapidly drying silt soils. As a rule it does not do well in calcareous soils or in heavy clay. Nevertheless, in the limestone districts of the Meuse department satisfactory results were obtained. As a general rule, however, healthy soils, sufficiently rich in water at the time of sowing are to be recommended.

**Climate.** — Manitoba wheat appears to be very resistant to drought; scorching was reported from the Ain department only. It does well in the mountains, at a height of 5 250 feet in the Upper Alps and 2 300 feet in Upper Savoy.

**Cultural Methods.** — *Preparation of the soil.* — Manitoba wheat requires a very clean tilth in order to give good results. In spite of its rapid

(1) For the experiments on Manitoba wheat see R. April, 1917, No. 326 and November, 1917, No. 1017. (Ed.).

growth it easily becomes weedy. Information obtained from all over France shows that the yield is satisfactory only if the ground is thoroughly prepared by two autumn ploughings and shallow cultivation in spring, before sowing.

*Manuring.* — Farmyard manure mixed with superphosphates seems to have given better results than chemical fertilisers alone.

*Sowing.* — Careful sorting of Manitoba wheat seed appears indispensable; the seed used in 1916 included at least four varieties, two of which were bearded. The small seeds only gave medium results. All directors of agricultural departments recommend close sowing in perfectly healthy and thoroughly drained soil. This condition explains the differences noticed with regard to the dates considered the best for sowing. The departments of Côte-d'Or, Drôme, Gard, Rhone, Manche, Meuse, Morbihan, Vienne and Gironde, advise sowing before the end of March. The February sowing in Upper-Vienne did exceptionally well, but the results obtained with late sowing were very good in the departments of Eure-et-Loire, Orne, Eure, Calvados, Indre, Nièvre, Pas-de-Calais, Sarthe. In the departments of Eure and Orne it was possible to sow as late as May 15th.

*Resistance to Rust.* — The enquiry showed clearly that Manitoba wheat is very resistant to rust. In the districts in which rust was rife, this wheat was either completely immune or much less attacked than the local varieties.

*General Results.* — The results were mediocre in Ariège, Aude, Dordogne, Doubs, Finisterre, Meurthe-et-Moselle, Morbihan, Upper Pyrenees, Lower Pyrenees, Seine-et-Oise and Tarn-et-Garonne. In all the other departments the results were good or very good, and the yields better than those of the local spring varieties, though not so high as those of the local autumn varieties.

35 — **Results of the Cultivation of the Carlotta Strampelli Hybrid Wheat in Rice Fields in Italy** (1). — MARCARELLI, B., in *Il Giornale di Riscicoltura*, Year 7, No. 17, pp. 213-215. Vercelli, September 15, 1917.

In 1914-1915, and again, in 1915-1916, the Vercelli Rice-growing Station carried out experiments in the cultivation of Carlotta Strampelli wheat. During the second year, the effect of the date of sowing and different quantities of seed were tested. Sowing carried out on October 15th. with 75.83, 89.21 and 98.13 lbs. of seed per acre, gave 24.82, 25.14 and 25.86 cwt. per acre; that carried out on October 25th. with the same quantity of seed gave 23.54, 24.50 and 24.74 cwt. per acre, and that of November 4th. gave 19.24, 19.16 and 17.82 cwt. per acre. The best harvests, then, were obtained with the earliest and thickest sowing. Cologne Veneta wheat, cultivated under the same conditions, yielded from 18-19 cwts. per acre (*Il Giornale di Riscicoltura*, Year 1, No. 19, pp. 291-296, October 15th., 1916).

In view of these good results, the Rice-growing Station provided farmers with a certain quantity of Carlotta Strampelli wheat to be grown ex-

(1) See also B. 1915, No. 167; R., 1916, No. 1175. (Ed.)

perimentally and compared with the varieties usually cultivated by them. Five farmers obtained the following results (very unfavourable year): —

1) Carlotta Strampelli	8.26 cwt. per acre	.	.	.	Gentil rosso	{	7.16 cwt. per acre
					Hybride inversable		
2) Carlotta Strampelli	10.24	"	"	"	Cologna Veneta	{	8.66 " " "
					Rieti		
3) Carlotta Strampelli	15.58	"	"	"	Cologna Veneta	{	12.08 " " "
					Varesotto		
4) Carlotta Strampelli	11.94	"	"	"	The other varieties gave a rather lower yield.		
5) Carlotta Strampelli	16.10	"	"	"	Cologna Veneta		13.12 cwt. per acre.

In all cases the Carlotta Strampelli variety showed marked resistance to lodging, great vigour and slighter encroachment of weeds.

" With a few exceptions the wheats now grown in the Vercelli district are not well adapted to the conditions of soil and atmospheric moisture, to the fertility of many soils. The greater part were introduced from dry, or only partially irrigated districts, without special attention being paid to the characters of the varieties and their cultural requirements. Many have a limited proportion of culms and leaves, and they ripen too early to profit by the local climatic conditions, without having on that account a greater resistance to lodging and a good production. The varieties which, in rice fields, give a high yield, are those with tall, strong straw, with large leaves, a rapid growth from the beginning, so as to limit as much as possible the development of weeds, a rather late ripening period, and a large number of grains in proportion to the length of the rachis. In these respects Carlotta Strampelli wheat seems preferable to all others ".

**36 — Trials of Different Methods for the Cultivation of Winter Wheat, in the Great Plains Area, U. S. A. —** See No. 11 of this Review.

**37 — Rye-Growing in Uncultivated Rice-Fields ; in Italy. —** MARCARELLI, B., in *Il Giornale di Riscoltura*, Year VII, No. 17, pp. 210-213. Vercelli, September 15, 1917.

Rye-growing in rice-fields, without any previous preparation of the soil, can be carried out according to the rules recently suggested by Prof. NOVELLI for sowing wheat on uncultivated rice-land.

For this purpose the land should be wet and light, not too fertile, and not likely to pay for growing wheat. The rye is sown from mid-September to the end of October, before the rice harvest and just before turning the water away from the rice-field, taking care that the soil be quite free from water two days after sowing.

Where water is available, the rye may be sown on the rice stubble, previously inundating the ground, for, to obtain the best results with this method, the rye seeds must be sown on inundated ground, to obtain the greatest adherence of the grains to the muddy ground, followed by prompt germination. In this case, and if calcium cyanamide is available, a first nitrogenous manuring of 0.8 cwt. per acre may be given some days before admitting the water. In any case, from 18 to 23 lbs. more seed per acre than usual have to be sown to assure abundant vegetation and to make up

for the inevitable loss that occurs during germination and the young stages of the plant.

Immediately after the rice harvest, all the irrigating canals must be well looked after, deepening them a few inches and making new ones if there are not sufficient present. The dikes should be destroyed, and if mineral fertilisers are available, 62 to 72 lbs. of sulphate of ammonia and 1.6 to 2.4 cwt. of superphosphate should be given per acre, this is, if calcium cyanamide has not already been applied.

At the end of winter, before the rye has commenced its new growth, a slight harrowing should be given so as to break up and bury the stubble, and provide a good surface tilth. During the later stages of growth, no other attention need be given, save that the drainage ditches should be maintained in good order and a nitrogenous manuring applied if the cereal has suffered from the winter.

After the rye is harvested, the ground can be used for rice by employing transplanting, or, after sowing a cover crop of clover or some other leguminous plant in the beginning of March, a good cut of fodder may be obtained the same year.

The writer considers the advantage of substituting wheat by rye under the present exceptional conditions, when it is necessary to produce the greatest possible quantity of cereals. He further adds :

In many rice-growing districts of Piedmont, 1 acre of ground only produces 15 to 18 bushels of wheat, while it produces 22 to 24 bushels of rye. When there is a shortage of phosphatic manures and labour for cultivating the crop, rye is indicated as it requires less attention and is more hardy, quickly covering the ground and smothering weeds. This latter quality give the result that, when rice follows rye, the former requires less cleaning.

It should be remembered that rye is harvested 20 to 25 days before wheat, that is to say, at the period when the provision of wheat and, in general, cereals used for bread making, is the most required

[37-43]

44 — **The Indigenous Tan and Dye-Producing Plants of New Zealand.** — ASTON, B. C., in *The Journal of Agriculture*, Vol. XV, No. 2, pp. 55-62; No. 3, pp. 117-128. Wellington, August 20 and September 20, 1917.

The writer reviews the literature of the subject and draws attention to the fact that the ancient Maoris extracted the vegetable dyes, which they used for dyeing their garments, from the following trees and shrubs:—

Pure-black colours were obtained from the hinau small tree (*Elaeocarpus dentatus*) and the pokaka (*E. Hookerianus*), and to a less extent from the towai or beech trees (*Nothofagus fusca* and *N. Menziesii*) the tawhero-tree (*Weinmannia racemosa* and *W. sylvicola*) and hange-hange shrub (*Geniostoma ligustrifolium*).

Blue-black colours were obtained from the tutu or turakihi shrubs (*Coriaria ruscifolia*) and the mako-shrub (*Aristotelia racemosa*).

Red-brown colours were yielded by the toatoa or tanekaha tree (*Phyllocladus trichomanoides*) and makamaka-shrub (*Ackama rosaeifolia*).

Yellow, golden or brownish-yellow colours were got from the karamu-shrub (*Coprosoma* sp., probably *C. lucida* or *C. robusta*), raurekau-shrub (*Coprosoma grandifolia*) and puriri-tree (*Vitex littoralis*).

A blue colour was said to have been obtained from the whakou-shrub, or small tree (*Eugenia mairi*).

It is significant that, in the majority of cases, the colouring of the fibres was effected by the aid of plants extremely rich in tannin, or closely allied compounds.

The following data are given as regards modern experience and research in New Zealand tannins and dyes:—

**PLANTS FURNISHING DYES.** — *Aristotelia racemosa* (makomako, or wineberry). The bark supplies a blue-black dye.

*Tetragonia trigyna* (New Zealand spinach) yields a purple fluid used for ink. The fruit of *Schefflera digitata* and the juice of the root of *Phoridium* were also used for this purpose as well as for tanning.

*Coprosoma* spp. This genus of *Rubiaceae* (which includes 40 species), is restricted in habitat to Australasia, the Pacific Islands, New Guinea and Borneo. Many of its representatives are amongst the commonest and most widely distributed native shrubs. Their bark, and especially the cortex of the root, are of considerable tinctorial power, as in the case of *Coprosoma grandifolia* (orange-yellow); *C. linariifolia* (bright-yellow), *C. lucida*; *C. rotundifolia*; *C. rhamnoides*; *C. foetidissima*; *C. microcarpa*.

The preliminary tests of the writer have shown that there is reason to believe that closely similar, if not identical, dyes to those of madder (*Rubia tinctoria*) are to be obtained from *Coprosoma* roots, which have the economic merit of being larger than those of the former plant.

*Vitex lucens* (syn. *V. littoralis*) (puriri), furnishes, with various mordants, different yellow and brown tones. It has been suggested as a source of khaki dye for military material. Some of the lichens used for dyeing purposes in Scotland are also to be found in New Zealand: *Parmelia caperata*, *P. saxatilis*, *P. parietina*, *P. perlata*, *Lecanora tartarea*.

**PLANTS FURNISHING TANNINS.** — *Elaeocarpus dentatus*, (Hinau); the bark

contains from 19 to 20 per cent, of tannin; it is also used for dyeing.

*Elaeocarpus Hookerianus* (pokaka). The bark contains tannin. *Coriaria ruscifolia* (syn. *C. sarmentosa*) contains tannin in all parts of the plant.

*Ackama rosaeifolia* (Makamaka) — *Weinmannia sylvicola* (Tawhero or Towai), *W. racemosa* (Towai or Tawero in the north, Kamaki in the south Island) — *Eugenia maire* (Whakou or Wawhakou or Kiwaka), with 16.7 per cent. of tannin in the bark — *E. Smithii* with 10.7 per cent. — *Puschia excorticata* with 5.3 per cent — *Metrosideros* spp. (with 15 to 18.35 per cent of tannin in its bark). — *Fagus* spp. (syn. *Nothofagus*) — *Podocarpus spicata* (Matai or Black Pine) — *Dacrydium cupressinum* (red pine or Kimu) — *Phyllocladus trichomanoides* (celery-topped pine = Tanekaha, Toatoa) with 28.66 per cent of tannin in the bark — *Phyllocladus glauca* (Toatoa) and *Ph. Alpinus* (Mountain Toatoa) with tannin in its bark and phyllodia, and perhaps toi (Cordylina indivisa), supply a large amount of tannin.

46 — Sugar Cane Cultivation and the Manufacture of Sugar in the Republic of Salvador, Central America. — DOWNIE, HARRY A., in *The Louisiana Planter*, Vol. LVIV, No. 18, pp. 281-286. New Orleans, November 3, 1917

I. — CULTIVATION. — A description is first given of the methods usually adopted in Salvador: the cane is planted between rows of maize, and all work is done by hand. The author then describes the methods he adopted at La Labor de Duran, using machines, with which he obtained better results, both as regards increased yields and reduced labour. The method is as follows:

*Preparation of the land*, in June, July and August; a MOLINE plough, cutting to a depth of 9 inches was first used, then a MUES sub-soil plough, also cutting to 9 inches.

*Harrowing* (about 6), with disc harrow, every 15 days during summer to keep down weeds.

*Preparation of furrows for planting*; (best time September or October), the furrows were made in squares 7 feet apart both ways, so as to plant 900 plants per acre; these furrows were about 15 inches deep and the plough followed by a small two-horse plough, loosening the subsoil to a depth of about 6 inches.

*Planting*, the cane was planted at the intersecting points of the marking out, from 4 to 6 selected cuttings of 3 eyes each, planted slantwise, with the eyes looking up, and lightly covered

*Harrowing*, with a small-toothed harrow 6 days after planting.

During the rest of the rainy season a MOLINE plough cultivator was used every 10 days, going the way of the furrow till this was filled up, and afterwards all possible ways that the planting admitted.

During the dry season a MOLINE cane cultivator was used every 15 days.

The cost of work done by machine is only slightly less than that done by hand, but with machines 2 men per day can care for 6 acres, whereas 48 men are required to do the same work by hand, so that, by using machines, labour may be diverted to other work.

Not only was the crop (25 to 40 tons per acre) larger with machines, but the juice obtained was better, perhaps on account of the wide planting.

The cane was cut by hand, well down, if possible under the ground.

II. — MANUFACTURE OF THE SUGAR. — On small holdings the sugar is obtained by very simple methods. It is consumed in the country and known under the following names, which also indicate the quality and origin: — 1) *panela* or *dulce*, a dark brown product, sometimes rather lighter, containing all the molasses; 2) *pilon*, a white or brown sugar, run into moulds and clarified after boiling; 3) *Mascabado* or *Muscovado*, a light or dark brown sugar made on some holdings. To make this, the mascabado, immediately after boiling, is beaten up to a powder and dried in the sun. This sugar keeps well in the dry season, but goes wet in the rainy season.

It is difficult to estimate the cost of making these sugars, because the work is done by members of the family and friends, who are only paid very little.

Large sugar producers may be divided into two groups — the Trust group and — the outsiders. The trust group has 7 factories with a total production of 150 000 quintals. The outsiders have 9 factories producing 80 000 quintals. The trust group have enough land to raise their annual production to a million quintals, and the other group could do the same. There are also 1 000 000 acres of land suitable to sugar growing, an important factor in the progress of the industry.

Most of the sugar made by the large producers is consumed in the Republic, but a fair amount is exported to San Francisco.

No improved methods of manufacture are used. The smaller plants, where there is only a single crushing, yield about 125 lbs. per ton of cane; in the larger plants the yield is from 140 to 195 lbs. per ton of cane. There are three qualities of sugar: 1) good white sugar; 2) nearly white sugar; 3) light or dark brown sugar. The prices are respectively 12, 11 and 9 pesos (1) per 100 lbs. The cane is generally of very good quality, the juice running from 9° Beaume at the beginning of November, and 12 and 13° Beaume in February and March.

47 — *Capparis albitrunca*, a South African Plant Furnishing a Coffee Substitute. — See No. 5 of this Review.

48 — Production of Santal Oil in Mysore, British India. — See No. 5 of this Review.

49 — Tobacco Growing in Ireland (The Experiments in 1916). — KELLER, G.N., in *Journal of the Department of Agriculture and Technical Instruction for Ireland*. Vol. XVII, No. 3, pp. 461-466. Dublin, 1917.

The current scheme of tobacco experiments in Ireland, covering a period of ten years, and financed out of the Development Fund, was inaugurated in 1914.

The number of growers, the total areas cropped in 1916, at the two centres where experiments were conducted, and the quantity of tobacco produced at each centre are as follows:

(1) 1 peso = 18° 9d. at par. (Ed.).

Centre	No. of Growers	Acres	Preliminary Packed Wt. lb.
Adare, Co. Limerick; Mullacrew, King's Co.	51	83	(1) 11 500 (estimated)
Randlestown . . . . .	67	89	58 668

(1) 43 000 lb. dry weight were destroyed by fire on January 1st., 1917.

The varieties grown were: Copper King and Kentucky Black. At Randlestown centre, Rich Wonder and Yellow Mammoth, two varieties closely akin to Copper King and Kentucky Black were also grown on a commercial scale. The following varieties in addition were grown at Randlestown centre for the purpose indicated:

2 acres of Burley	{	For the production of bright pipe cutters
2 1/8 " Irish Gold		
4 1/4 " " "	{	For the production of a cigarette tobacco of the Virginia type.

At Adare centre three roods of Irish Gold and a half acre of Giourkioi were grown for the production of cigarette tobacco of the Virginia and Turkish types respectively. In addition to the seven varieties which were grown on a commercial scale, tests were conducted on a small scale at one centre with two varieties and three hybrids.

The results of experiments with varieties were as follows:

*For Roll and Plug.* — No variety tested proved better than Copper King, which had a superior habit of growth.

*Bright Pipe Cutters.* — Broad Leaf Burley and Irish Gold proved quite suitable for the production of bright pipe cutters, but both varieties were very susceptible to root rot, and also proved much more difficult and expensive to cure than heavy dark tobacco.

*Cigarette Tobacco.* — A severe attack of root rot seriously interfered with the experiments with the Irish Gold variety for cigarette purposes. At one centre a half acre of Giourkioi, a Turkish variety, was planted very late and gave a very poor return.

The results of the year's work with bright tobaccos, suitable for cigarette and pipe cutters, emphasized the fact that the production of these types of tobacco involves greater difficulty and risk than the production of heavy dark tobacco.

Experience and careful tests have shown that it is very difficult to cope with the root rot disease, caused by the fungus *Thielavia basicola*. Some crops were imperceptibly damaged, others were almost completely destroyed. Tobacco grown on moory land and rich friable loam suffered least.

For the rehandling of the 1915 crop both centres were equipped with the latest pattern of PROCTOR continuous, automatic, redrying and ordering machine.

The experiments indicate that a Proctor machine would be a very effi-

cient and economic instrument in the preparation for market of Irish tobacco if the growing of the crop were on an extensive and permanent basis. The rehandling equipment at each centre represents a capital outlay of, approximately, £ 2000.

Under commercial conditions, such as exist in America, the annual charge for this equipment would be distributed over the produce of 1000 acres or more.

Any tobacco produced in 1915, which was not sold to factories controlled by the experimenters, was disposed of through tobacco brokers and merchants.

In 1915 the preliminary packed weight of the tobacco grown on the total area of 225  $\frac{1}{8}$  acres was 144 289 lb. Of this quantity a total of 132 689 lb. has been sold at an average price of 7d. per lb. The cost of growing pipe tobacco in 1915 ranged from 3d. to 11.8d. per lb. and the cost of rehandling at the different centres ranged from 1.6d. to 3.3d. per lb. These figures are exclusive of any charges in respect of capital or supervision. The packing and bonding of the 1916 crop has not yet been completed. No difficulty is anticipated in selling the crop, the prohibition of the importation of tobacco having strengthened the demand and increased the prices for Irish grown tobacco.

51 — The Leguminosae *Dolichos melanophthalmus* and *D. sesquipedalis* as Vegetables in Italy. — RAGIONIERI, ATTILIO, in *Bullettino della R. Società Toscana di Orticultura*, Year XLII, No. 10, pp. 149-151. Florence, October 15, 1917.

HORTICULTURE

The dolichos cultivated in Tuscany under the names of "fagiolini dall'occhio" or "fagiolini di Sant'Anna", belong to a mixture of numerous forms and varieties of *Dolichos melanophthalmus*. By separating and selecting them it would be easy to obtain improved species.

For over a century the asparagus bean ("fagiolo asparagio" or "dolico gigante" or "fagiolo di Cuba"), considered to be an improved species of *Dolichos sesquipedalis*, has been cultivated in Tuscan gardens. It is a climbing plant which reaches a height of about 10 feet. The green pods, about 18 to 20 inches long (when quite ripe they are about 31 inches long) are eaten. They are grown in soil dug deeply at the beginning of winter and manured with well rotted manure, superphosphate and a little potassic fertiliser. Sowing is carried out in mid-April in trenches from 35 to 39 inches apart, the seeds are placed two or three together at distances of about 10 inches. When the plants are large enough they are hilled up, usually after an application of liquid manure. After this all that remains to be done is to fix the plants on to their supports (cane fences, etc.) and to water them abundantly. The occasional application of liquid manure when watering during the summer improves the yield, which starts towards the middle of July and continues till the first white frosts.

Crossings between the various *Dolichos* are very easy, whereas those between the various *Phaseolus* are very difficult. Crossing *Dolichos* and *Phaseolus* never succeeded.

- 52 - **A Simple Method for Forcing Rhubarb in the Open Air.** — DUFOUR AUGUST, in *Bulletin de l'Association des Marchés de Genève*, Year XXVI, No. 52, pp. 12, 13 + 1 plate. Geneva, November, 1917.

Among the many methods in use for forcing rhubarb in the open air, a very simple one consists in using an old cask, the bottom or end of which has been removed, the other being left.

After having dressed the foot of the rhubarb in November with fresh horse manure, the cask is placed over the roots and surrounded with a sufficient quantity of stable manure and litter to warm the plant and help the leaves to grow. A heat of from 25 to 30° C. is thus obtained. If too great a heat is to be feared air is let in through the bung-hole.

The following English and American varieties are distinguished by their earliness and are well adapted to forcing: — Early Laxton Rhubarb, deeply coloured; Hotdays Giant; Hanke's Champagne; Daw's Champion; Johnston St. Martin; Dancer's Early Scarlet; Mitchell's Royal Albert; etc. (1).

#### FORESTRY

- 53 - **The Work of the Philippine Bureau of Forestry.** — FISCHER, A. F. (Director of Forestry), in *Annual Report of the Director of Forestry of the Philippine Islands for the Fiscal Year Ended December 31, 1916*. The Government of the Philippine Islands Department of Agriculture and Natural Resources, Bureau of Forestry, pp. 83. Manila, 1917.

This Report of the Director of Forestry of the Philippine Islands shows, in the first place, that the Bureau has continued the propaganda work carried out to show the people the benefits to be derived from the forest laws. The wood expert has also done important work in the study and identification of the trees and their products (2). Considerable surveying and inspection work was also done. Besides the ordinary work of the Administrative Division, mention must be made of the Division of Investigation, whose staff also gives instruction in the Forest School. The chief work carried out by this Division consisted in reconnaissance work, supplying information for the forest maps, dendrology (flora of the forest reserves devoted to experimental work; check list of woody plants of the Philippines; research on rattan [*Calamus Rotang*], rubber and bamboo plants), silviculture (growth studies, silvical notes, reproduction studies, planting, seed collection).

Reforestation is of paramount importance in the Philippines, for over 40 % of the total area is covered with cogon grass (*Imperata exaltata*), which is useless for grazing, is a fire menace, exhausts the soil and is a breeding place for locusts. Its destruction, which is necessary to protect the crops, entails great expense. A tree, ipil-ipil (*Leucaena glauca* Benth.), has been found which will kill out cogon grass within two years. Besides this tree, hunbang (*Aleurites moluccana* Willd.) and bagilumbang (*Aleurites trisperma* Blco.) were also planted.

The lumber trade improved in 1916. The principal markets for this product are those of Hongkong, China and the United States, besides the

(1) See also R. September, 1917, No. 824, p. 1260, under RHUBARB. (Ed.) (2) See: SCHNEIDER E. E. (Wood Expert, Bureau of Forestry), Commercial Woods of the Philippines: Their Preparation and Uses, in *Department of the Interior, Bureau of Forestry, Bulletin* No. 14, pp. 274 + 12 figs. 8 plates. Manila, 1916.

local market. The shortage of coal and its high cost gave, at the end of 1916, a great impulse to the production of fire wood, which is also used on the railways. In 1916, the production of fire wood reached 292 336 cubic metres (1 cubic metre = 424 board feet).

The Bureau of Forestry of the Philippine Islands administers 16 million hectares of forests, and includes 201 employees of all grades. In 1916 the revenue was distributed as follows :

Appropriations . . . . .	321 205.20 pesos (1)
Revenue . . . . .	494 447.65
Expenditure . . . . .	285 708.09
Surplus . . . . .	208 739.56
Percentage of expenditure to revenue . .	58 %

The following data on the utilisation of the public and private forests in 1916 are of interest.

	Public forests	Private forests
Timber . . . . .	341 445 cubic metres	2572 cubic metres
Firewood. . . . .	292 336 "	84 428 "
Charcoal. . . . .	2 233 "	1 815 "
Dyewood . . . . .	2 281 466 kg.	—
Tan bark . . . . .	1 543 686 "	2 237 kg.
Dye bark . . . . .	93 057 "	8 505 "
Wood oils . . . . .	63 353 "	—
Gum mastic . . . . .	1 089 448 "	—
Gum elemi . . . . .	251 657 "	—
Gutta-percha . . . . .	19 077 "	—
Split rattan . . . . .	3 112 126 "	2 187 kg.
Gogo . . . . .	157 324 "	51 "

The woods most commonly used for timber are those of the Dipterocarpaceae ("lauan", "apitong", "tanguile" or Philippine mahogany, etc.) (2). In 1916 the exports were :

Timber . . . . .	39 954 cubic metres
Copal . . . . .	1 143 938 kg
Elemi . . . . .	104 311 "
Gutta-percha . . . . .	29 962 "
Rattan . . . . .	82 100 pesos

## LIVE STOCK AND BREEDING.

54- Studies on Fagopyrismus and Similar Affections in Canada. — BRUCE, E. H., in the *Journal of the American Veterinary Medical Association*, Vol. 411, No. 2, pp. 189-194, Ithaca, N. Y., November, 1917.

HYGIENE

Fagopyrismus is an erythema of the unpigmented skin, often accompanied by nervous symptoms and which sometimes ends fatally. Its production requires the following factors: 1) unpigmented skin, 2) in-

(1) peso = 2s. 0 1/2 d. at par. (2) See B. 1915, No. 823 (Ed.).

gestion of buckwheat, 3) direct sunshine. Somewhat similar conditions may be produced by *Medicago*, *Trifolium*, *Hypericum* and *Polygonum*. The writer had occasion to study an outbreak of fagopyrismus in Yorkshire sows and young pigs belonging to the University of British Columbia, which had been running on a pasture with buckwheat in flower for only 24 hours in August 1917.

*Symptoms of the disease.* In mild cases, there is erythema and slight inflammatory swelling accompanied by intolerable itching, the region of the head and ears being the most commonly affected. In the severer cases, there may be some disturbance of breathing, digestive trouble, and symptoms of brain affection. Death may result in 12 hours. In most cases, recovery takes place in a few days.

*Treatment.* Affected animals should be moved at once into the shade. In severe cases, treatment should be given to reduce inflammation.

In May 1916 a herd of Holstein heifers, belonging to the Agassiz (Canada) Experimental Farm, which had been running in woody pasture where there were large numbers of different species of *Polygonum* were found to be suffering from the symptoms of fagopyrismus. The parts directly exposed to the sun's rays were affected, the dermatitis being confined to the white parts of the skin. This fact induced the writer to study the disease.

On July 18th, 3 white pigs were placed in the shade and fed until the 28th. as follows: — one served as a control and was fed on mixed grass and shorts, the 2nd. on shorts and red clover (*T. pratense*); the 3rd received shorts and *Polygonum Persicaria*. From July 28 to August 4, the pigs were placed in pens so situated that they could not get out of the sun. The next day, the ears of all the pigs were reddened, those of the 2nd. and 3rd. pigs being slightly the worst.

In a 2nd. experiment, made with the same animals, one was fed for 16 days on a diet of *Polygonum Hydro Piper* without any results being obtained. A yearling Holstein bull, with a great deal of unpigmented skin, was kept from August 10 to 28 in a pen in the open and fed exclusively on *Polygonaceae*: *Polygonum Persicaria*, *P. Hydro Piper*, *P. aviculare*, *P. acre*, *P. hydro Piperoides*. No ill effects, however, ensued.

In conclusion, there experiments do not confirm the opinion advanced by different writers (PAMMEL, LONG, MÜLLER, FRIEDBERGER, FRÖHNER, etc.), that other species of *Polygonum* are toxic, as well as *P. fagopyrum*.

55 - **Eradicating Tall Larkspur on Cattle Ranges in the U. S. National Forests** (1). — ALDOUS, A. E., in *United States Department of Agriculture, Farmer's Bulletin*, No. 826 pp. 23, 8 figs., 4 tables. Washington, August, 1917.

Poisoning by tall larkspur (*Delphinium exaltatum*) causes heavy loss of cattle each year in the National Forests of the United States. During the last 3 years, 5 500 head of cattle, estimated at \$ 300 000, were lost annually through poisonous plants; about 90 % of this loss is attributable to tall larkspur. The bulletin describes the efforts made to eliminate the

(1) See R. January, 1917, No. 54. (Ed.)

loss caused by this plant. Experiments made in 1913 and 1914 in the forests show that grubbing out the plants is the most effective method. The work of eradication was continued in 1915 on about 14 000 acres of cattle range in the National Forest.

The work is done by grubbing out the greater part of the root system, including the main and lateral roots. The depth depends on the size of the roots; for medium sized roots (about 2 feet) the depth should be 8 inches, for shorter roots, 6 inches suffice. Very large bunches often have large, shallow lateral roots, which should be removed to at least 4 inches from where they leave the main root, for a little more than 6 % of the larkspur survive the first eradication and grow again from the roots which have been insufficiently removed. Eradication should be carried out during two consecutive years.

The work is best carried out early in the season, as soon as the plants have grown sufficiently to be easily recognised. The plants may be left spread out in the sun for a week, after which they are so dry that the cattle will not eat them. This method is preferable to that of piling the plants and burning them, and also requires less labour.

The tool used is determined by the nature of the ground, a pick mattock, or hoe with the spur cut off and the blade drawn out to about 9 inches, may be used.

The cost of the first eradication varies from \$ 3.65 to \$ 10.10 per acre according to the number of plants, nature of the soil, and whether the range is free from rocks, willows and brush. The cost of the second eradication does not exceed \$ 1 per acre.

Grazing by sheep, which are not susceptible to the poisoning, has only a limited success which depends chiefly on the choice of the most favourable period, the spring.

Fencing off the infested land by drift fences is more costly than grubbing and should only be adopted if horses or sheep are available to graze the areas from which the cattle are excluded.

56 - **The Properties of the Serum of Animals Hyperimmunised against Glanders, and the Choice of Animals for the Preparation of Such Serum Rich in Suitable Antibodies.** — BERTETTI, E. and FINZI, G., in *Atti della Reale Accademia dei Lincei, Rendiconti, Classe di scienze fisiche, matematiche e naturali*, Series 5, Vol. XXV, Part 5, pp. 131-135. Rome, September, 1917.

The writers have attempted to prepare anti-glanders sera rich in antibodies by using the following animals: the *ass*, which is very susceptible to glanders, and when infected naturally or experimentally, usually suffers from the acute form of the disease; the *mule*, in which the disease is usually very acute (though acute cases are fairly common in that animal and chronic cases are not rare); the *horse*, in which the disease is usually chronic; the *ox*, which is naturally quite immune.

The experiments were as follows:

*Immunity obtained by using bacilli killed by chemical means.* — On August 30, 1916, a horse received an intravenous injection of a 7- to 8-day, half-culture on agar of glanders bacilli killed with a solution of bichloride

of mercury. The following injections were made in increasing doses; at the 12th. injection 5 agar cultures were inoculated. The first injections were given close together; afterwards they were given every 5 days up to the end of January, 1917, when they were given every 12 or 13 days.

*Immunity obtained by using bacilli killed by heat.* — On August 28, 1916, a horse, mule and an ass were treated like the horse mentioned above, with the difference that the bacilli were killed by heat.

*Immunity obtained by means of bacilli killed by heat and by a malleinic toxin.* — Two horses and an ass were treated with bacilli killed by heat and by malleinic toxin obtained by a special process.

*Immunity conferred on cattle by means of bacilli killed by heat and virulent bacilli.* — Two oxen were immunised subcutaneously; the first received injections of very virulent bacilli grown on agar; the second received cultures from the same stock, but killed by heat (1 to 6 abundant cultures in Petri dishes). The injections were made regularly every 5 days for about 8 months. The oxen supported the immunising treatment very well.

**RESULTS.** — In August 1917, the subjects under treatment yielded serum having the following specific qualities: very energetic *precipitating* power; *agglutinating* power very manifest, even at considerable dilutions, e. g., of 1 : 10 000 to 1 : 20 000 (the heat test showed the specific nature of the agglutinins of these sera, in showing that they were such as would confer immunity); this serum has abundance of a specific *sensitizing* agent, easily recognisable either in presence of *Bacillus mallei*, or in presence of different bacillary extracts.

The animals under treatment did not all yield a serum of equal activity. Those inoculated with broth or agar cultures of *Bacillus mallei* and with mallein gave quite inactive serum.

If the *precipitating*, *agglutinating*, and *sensitizing* powers of the various sera obtained are classed by means of numbers from one to ten, the following scale is obtained: serum from oxen, 10; serum from horses, 8; serum from mules, 4; serum from asses, 1 to 2. The power of fixing alexins, precipitating malleinic poisons and agglutinating the various races of *B. mallei* is perfectly proportional for all the sera.

**CONCLUSIONS.** — 1) It is possible to obtain from the different animals (ox, horse, mule, ass) anti-glanders sera with strong precipitating powers in regard to various malleins and cultures of the bacillus obtained by filtration, of high agglutinating power and containing specific sensitizing agents, easily recognisable in presence of the causal organism or its various extracts.

2) The existence of a more or less great individual disposition to glanders has an inversely proportional effect in the production of anti-glanders antibodies. In fact, these antibodies, which show the work performed by the organism in order to acquire immunity, are more abundant in ox-serum and diminish progressively through the horse, mule and ass.

3) According to the writers, the fact the oxen are immune to the disease should not be considered as being related to the lack of affinity

between *B. mallei* and the cellular units of the organism, as these latter are certainly and actively affected by *B. mallei*.

4) It is inadvisable to treat the animals with agar or broth cultures of the glanders virus together with mallein, with the intention of producing a complete serum, for the soluble products of *B. mallei* contained in suspension in the broth cultures, or the crude mallein injected, possibly being modified only slowly, finally neutralise *in vivo* the antibodies produced by the bodies of the organisms, or else the haptophoric (1) group of the precipitin former absorbs and fixes the precipitin.

5) The precipitins contained in the anti-glanders sera prepared by the writers are thermolabile: temperatures between 55 and 60° C destroy the functional, precipitogenous, and active group of the precipitins, which are changed into precipitoids.

The work was carried out in the "Glanders Research Laboratory" of the 3rd. Italian Army. The writers place their anti-glanders sera at the disposal of other workers.

#### 57 - Endoglobular Parasites Causing Diseases of Animals in Russian Turkestan. —

YAKIMOFF, W. L. and collaborators, in the *Bulletin de la Société de Pathologie exotique* Vol. X, No. 4, pp. 302-311. Paris, April 11, 1917.

The authors have observed the following haematozoan diseases of animals in Russian Turkestan: —

A PIROPLASMOSES. — 1) Bovine piroplasmosis, due to *Piroplasma bigeminum*, easily curable by injections of trypanoblué.

2) Equine piroplasmosis, caused by *P. caballi*; treatment with trypanoblué has given good results.

(1) According to EHRLICH's side-chain theory (1885), the cell is composed of a central molecular complex upon the preservation of which the existence and energy of the whole cell depend. Branching off from this central element are atomic groups, the so-called "side-chains" or "cell-receptors". These receptors are differently composed and each possesses its own specific affinity for food molecules brought to the cell by the circulation. These receptors bind in turn the food molecules to the cell itself, and as these are taken up and utilised in the cell metabolism, so are also toxins which may be brought to the cellular elements by the body fluids. Thus there are *nutro-receptors*, which take up nourishment, and *chemo-receptors*, which attract chemical bodies. The combination of nutro-receptor with the food molecule is temporary; but with the chemo-receptors, if the toxin be not immediately destroyed, the cell sacrifices the receptor to which the toxin is attached. The cell then increases the number of receptors, which may be produced in such number as to be liberated from the cell, and if toxin molecules be present a union takes place between the two. The injection of an immune serum is, therefore, equivalent to injecting material containing side-chains.

Ehrlich divides the side-chains, according to their structure into 3 groups: 1) receptors containing a single combining or haptophoric group, which enables them to unite with a corresponding group of their respective antigens, such as *antitoxins*, *anticomplements*, *antiserments*, etc.; 2) receptors possessing the same qualities as the first, but having an additional group, the *ergophoric* group, and by means of these the antigen is further acted upon; to this group belong *agglutinins* and *precipitins*; 3) *amboceptors*, so called on account of their possessing two combining groups; the first belong to the haptophoric group, uniting the antigen to the cell, and the second to the complementophilic group, which combines the complement of the serum. Cf. E. WALLIS HOARE, *Veterinary Therapeutics*, 3rd edition, pp. 545-547. London, 1916. [Ed.]

3) Sheep piroplasmosis, in which the *Piroplasma* is pearshaped.  
 4) Goat piroplasmosis.  
 5) Wolf piroplasmosis, which seems to be very common,  $\frac{2}{3}$  or  $\frac{3}{4}$  of the animals examined at the abattoirs of Taschkente and Boukhara being attacked, the majority only slightly; the parasites seem to resemble *Theileria*; in one case a parasite was found which was morphologically similar to *P. canis*, though it had not been found in dogs (the authors have examined practically only town dogs).

B. THEILEROSIS. — 1) Bovine theilerosis occurs in two forms: acute and chronic; the first form appears to last several days, then becoming chronic. The disease is probably caused by *Theileria mutans* or some related organism.

2) Sheep theilerosis, caused by *Th. ovis*.

3) Camel theilerosis, for which the authors have founded the species *Th. camelensis*.

4) Fox theilerosis.

C. NUTTALLOSES. — 1) Horse nuttalliosis, caused by *Nuttallia equi*.

2) Ass nuttalliosis.

D. ANAPLASMOSIS. — 1) Bovine anaplasmosis, due to *Anaplasma marginale*; described as marginal points, nearly always associated with theilerosis.

2) Horse anaplasmosis.

3) Dog anaplasmosis.

58 - Notes in Regard to Bots, *Gastrophilus* spp. — HALL, MAURICE C, in the *Journal of the American Veterinary Association*, Vol. LII, No. 2, pp. 177-181. Ithaca, N. Y., November, 1917.

The experiments described were carried out at the Research Laboratory of Messrs. PARKE, DAVIS and Co., Detroit, Michigan. In order to make sure that the parasites had been expelled the treatment was, in some cases, followed by a post-mortem examination. Carbon bisulphide (recommended by PERRONCITO and BOSSO in 1894, and by many later authors) is very efficacious against bots, expelling all the larvae. The U. S. Department of Agriculture recommends 4 doses from 10 to 12 mg. each, administered at intervals of 1 hour. The author, in his experiments, gave a dose (in capsule) of 12 mg. followed by a second dose in 1  $\frac{1}{2}$  hours, and, 1  $\frac{1}{2}$  hours later, 800 mg. of linseed oil; a few days later 3 doses of 12 mg. each were given at intervals of 1 hour.

Chloroform and oil of chenopodium are of no value against bots.

*G. intestinalis* (*G. equis*) may cause myiasis in dogs to which are fed well developed larvae from the stomach of the horse. *G. nasalis* and *G. hemorrhoidalis* only adapt themselves to the dog to a limited extent.

59 - Observations on a Contagious Camel Disease Called "Jhooling" in British India. — CROSS, H. E., in *Agricultural Research Institute Pusa, Bulletin* No. 72, 2 pp. + 4 fig. Calcutta, 1917.

"Jhoolak" or "Jhooling" is a contagious disease of camels manifesting itself in the formation of local tumours, hot and painful, of a fibrous character, and terminating in suppuration and raw patches. The disease is widely

distributed throughout the Punjab. It usually occurs in cold weather, but is met with occasionally in hot weather. The causal organism has not yet been isolated, though it is probably a fungus. Horses, buffaloes and cattle kept in contact with camels suffering from Jhooling do not contract the disease, nor can it be produced in them by inoculation of emulsion of the lesion, nor by rubbing portions of the lesion on their skin, whether the skin be scarified or not. On the other hand, healthy camels kept in contact with camels suffering from Jhooling contract the disease rapidly.

As a preventive measure, the writer advises the isolation of infected animals. The best treatment, and one which gives very satisfactory results is the following:—A strong red iodide of mercury blister should be applied, and after 3 days washed off with soap and water. The diseased areas should then be excised and finely powdered permanganate of potash applied. Three dressing at intervals of 4 days are usually sufficient.

60 – **The Mortality of Rabbits in Wet Years in Consequence of Coccidiosis.** —

RAILLIET, in *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. 3, No. 34, pp. 979-986. Paris, November 7, 1917.

On account of the importance of rabbit breeding on account of the war, and in consequence of the high mortality of this animal in wet years, the writer shows that the chief cause of the mortality is *coccidiosis*, which occurs in two chief forms: *hepatic* and *intestinal*; both of which may be *acute* or *chronic*.

The symptoms and course of the disease are described (being practically identical in both forms); the life-cycle of the parasite is then described. The parasite only produces sporozoites (the agents of infection) when the environment is damp, which explains why coccidiosis is prevalent in wet years.

The preventive measures for controlling the disease are described: isolating or destroying diseased or suspected animals; burning or deeply burying the corpses or viscera; disinfecting the litter with water containing 40 grms. of sulphuric acid per litre or sprinkling it with quicklime; disinfecting the cages by washing them in boiling water; not crowding the rabbits together; early separation of young from adult animals; placing the hutches in healthy, well ventilated and dry places; giving dry or cooked food in preference to green stuff, particularly when earthy and wet; putting the food in trellised mangers, placed at a certain height; providing clean, fresh water in drinking troughs that are easy to clean.

As regards treatment, the writer states that he knows no sure one. Some veterinarians prescribe atoxyl and sodium emetic (sodium tartrate and antimonyl) but its use is not safe. A less dangerous remedy is advised by English and American writers; such is a solution of iron sulphate or a solution of *cutch* (extract of *Acacia catechu*) both given at the rate of about 20 centigrammes per litre of drinking water. An Italian veterinarian, SANLORENZO, has recently announced the complete cure of intestinal coccidiosis of the bull by means of thymol given up to the dose of 15 gm. per day; doses of 25 to 50 centigrammes might be tried with the rabbit.

- 61 — **Intestinal Parasites of Poultry, Their Prevention and Treatment.** — WICKWARE, A. B., in *Dominion of Canada, Department of Agriculture, Health of Animals Branch, Bulletin*, No. 25, pp. 13 + 3 plates. Ottawa, 1917.

This bulletin was written for poultry breeders as it was found that, of all the diseases of poultry, those caused by intestinal parasites cause the greatest loss. The annual money losses from preventable causes is at least 10 % of the yearly production of the poultry industry, i. e., about 5 million dollars.

After a short description of the Cestodes, Nematodes and Trematodes found in poultry and the symptoms of infection, the author summarises the various treatments tested by him which may be recommended. One or two teaspoonfuls of turpentine per fowl seems the most efficacious cure and is one which is easily applied. In order to avoid the irritation caused by the turpentine when given through the mouth it is preferable to use a piece of rubber tubing about  $\frac{1}{4}$  inch in diameter. After the tubing has been oiled it is passed gently into the mouth and gradually worked down the gullet into the crop. The turpentine may be passed through the tube by means of a small medicine dropper.

FEEDS  
AND FEEDING

- 62 — **Feeding Studies: The Causes of the Dietary Insufficiency of Certain Rations.**  
— See No. 2 of this *Review*.

- 63 — **On the Impossibility of Watering the Milk by giving Large Quantities of Water to the Cow.** — PORCHER, CH., in *Annales des Falsifications et des Fraudes*, Year 10, Nos. 105-106, pp. 304-320. Paris, July-August, 1917.

On account of the large number of experts and chemists who still believe in "polylactie" or "mouillage au ventre", and the danger of such a belief from the point of view of the repression of fraud, the author (Professor at the Veterinary School of Lyons) shows how incorrect that idea is, according to which, the ingestion of large quantities of water by a lactating female is followed by a veritable watering of the milk.

He recalls the physiology of lactation, insisting on the fact that milk is secreted, not excreted. The researches, experiments and conclusions of MALPEAUX, MALLÈVRE, REGNARD, etc., are quoted.

The note concludes that "polylactie" (watering the milk through the cow) does not exist, and that it is nonsense, both physiologically and experimentally, that could not be used as the basis for any reasonable judicial decision.

- 64 — **Methods for Approximating the Relative Toxicity of Cottonseed Products** (1). — CARRUTH, FRANK E., in *The Journal of Biological Chemistry*, Vol. XXXII, No. 1, pp. 87-90. Baltimore, Md., October, 1917.

The work described was carried out at the North Carolina Agricultural Experiment Station, West Raleigh.

In collaboration with Mr. WITHERS, the author undertook investigations into the cause of cottonseed meal poisoning. These investigations, which have not yet been published, showed that, as a rule, the relative

(1) See also *R* August, 1917, No. 741.

(Ed.)

toxicity of cottonseed meals varies with the extent to which the raw cottonseed kernels are cooked in the oil mill.

The raw kernels are highly toxic to animals since they contain about 0.6 % gossypol, a highly poisonous phenolic plant pigment. On cooking with moist heat, as in the hot pressing processes, preparatory to expressing the oil, the glands containing gossypol are disintegrated, and the gossypol spreads over the surface of the seed tissue and apparently undergoes a change which appears to be a partial oxidation. This change takes place very rapidly, for some meals which have been cooked for 20 to 30 minutes only are not markedly toxic for rats. The cooking process change the ether-soluble and oil-soluble gossypol to a substance which, *in the meal*, is no longer soluble in either ether or oil, possibly because it is in some way chemically combined with some constituent of the meal (protein). Its presence in large amounts in ether-extracted cottonseed meal may be proved by treating the meal with hot alcoholic potash. The supernatant liquid contains the substance which, like gossypol, soon oxidises, producing a beautiful blue colour. The author calls this substance, which is much less toxic than gossypol, "D" gossypol.

Cold pressed meal is not more toxic than hot pressed meal; this is due to the fact that, in cold pressed meal, about  $\frac{3}{4}$  ths. of the total gossypol of the seed passes into the oil. Thus, whereas hot pressing greatly reduces the toxicity of the cotton seed by producing a chemical change, cold pressing reduces it by passing the gossypol into the oil.

If the gossypol is present in the meal it may be extracted by ether or detected by the following microscopic method.

1) *Sulphuric Acid test for unchanged gossypol.* — A little of the meal is sprinkled on a glass slide and treated with a drop of concentrated sulphuric acid. The result is observed through the low power of the microscope. If numerous red areas appear where the acid touches the more or less broken up "glands", toxic unchanged gossypol is present. Thoroughly cooked meals and cottonseed flour show very few and very small red areas.

2) *Quantitative determination of the gossypol present in cottonseed meal using aniline as a precipitant.* — This method is based on the fact that the unchanged gossypol present in the meal is easily extracted by ether, together with the oil. Gossypol forms a very slightly soluble compound with aniline, which separates from the oily extract and may be filtered out and weighed.

**65 - Food Value of the Waste Leaves of Different Varieties of Cabbage; Investigations in Holland.** — DE VRIES, J. J. OTT., in *Nederlandsch Landbouw-Weekblad*, Year 26, No. 45, Supplement p. 1. Schiedam, November 10, 1917.

In 1912 the cauliflowers grown in Holland covered an area of 6 000 acres, red cabbage 4774 acres, and white cabbage and common cabbage 4885 acres. Estimating the quantity of waste leaves per acre at 5  $\frac{1}{2}$  tons for cauliflower and from 8 to 8  $\frac{1}{2}$  tons for white and other hearted cabbage, about 120 000 tons of such leaves are produced annually in Holland.

In order to estimate the food value of this waste, analyses were made at

the Hoorn Agricultural Experiment Station. The results obtained are given in Table I.

TABLE I. — *Composition of waste stems and leaves of different varieties of cabbage.*

	Cauli- flower stems	Leaves of cauliflower		Leaves of red cabbage			Leaves of white cabbage	
		I	II	I	II	III	I	II
Dry matter . . . . .	16.6 %	11.2 %	—	12.0 %	12.1 %	9.9 %	11.0 %	10.8 %
<i>Composition of dry matter :</i>								
Ash . . . . .	9.0	24.8	24.3	23.2	18.4	10.5	25.2	22.1
Ash insoluble in water . . . . .	—	14.8	17.1	15.4	12.6	4.5	17.6	13.7
Fibre . . . . .	55.0	11.0	16.9	14.7	14.1	15.2	12.6	12.9
Fat . . . . .	0.8	5.1	3.5	4.8	5.4	3.4	4.2	4.2
N-free extract . . . . .	24.9	33.4	33.5	41.2	43.0	14.8	42.7	2.9
Crude protein . . . . .	10.3	25.7	21.8	16.1	19.1	26.1	15.3	17.9
Pure protein . . . . .	9.3	17.1	18.2	11.4	13.9	15.8	10.4	12.8
Digestible protein . . . . .	4.5	14.1	13.4	9.3	11.7	14.3	8.4	10.4

These analyses show that : —

1) The food value of waste cauliflower leaves may be compared to that of brewers' grains.

2) Waste leaves of red cabbage have a food value double that of clover hay.

3) Waste leaves of white cabbage have a food value double that of good meadow hay.

Analyses of the different cabbage wastes for their fertilising value gave the results shown in Table II.

TABLE II. — *Percentage of fertilising elements (compared with the dry matter) in the waste leaves of various cabbages.*

	Cauliflower leaves	Red cabbage leaves	White cabbage leaves
	%	%	%
Nitrogen . . . . .	3.6	2.8	2.6
Phosphoric acid . . . . .	0.54	0.58	0.67
Potassium . . . . .	1.5	2.0	1.6
Lime . . . . .	8.2	7.8	8.6

According to calculations based on present day values, the value of such leaves as a food exceeds their value as a fertiliser.

Feeding experiments carried out with this waste on two cows at the Hoorn Experiment Station, show that leaves of cauliflower and white cabbage produce hardly any disagreeable smell or taste in the milk; red-cabbage leaves seem to have a greater influence in this respect, but it is probable

that the milk takes the characteristic taste and smell of the cabbage as a result of being left too long in the byre where the cabbage waste is kept.

The taste and smell of the cabbage may also be passed to the milk from the hands of a milker who has touched the leaves.

Cabbage leaves seem to have no bad influence on the fat content of the milk. During the experiments the cows out at pasture ate an average of from 66 to 88 lbs. of cabbage leaves daily. No bad effect was noticed on the cream. Further experiments will be made at the Hoorn Station to determine the food value of these leaves when kept in silos.

66 — **Acorns and Beechnuts as Food for Cattle** (1). — *Feuille d'Informations du Ministère de l'Agriculture*, Year 22, No. 44, pp. 10-11. Paris, October 30, 1917.

I. *Acorns*. — The latest work on the composition of acorns has shown them to be poor in albumin, yet very nutritious on account of their high content in nitrogen free extract (starch and sugars). They are poor in lime, phosphoric acid and ash. They are characterised by tannic acid, and a bitter element, *quercite* or acorn sugar, substances capable of causing gastric trouble, particularly constipation, if fed to animals in excessive quantities. These injurious effects are increased if the acorns are badly kept or mouldy.

Acorns are not complete foods, and pigs fed on them alone without any other protein food, suffer from cachexia of the bones, many of which fracture, and they lose in weight; their intestines turn greyish.

As a supplement to other rations acorns produce no harmful effects, and are to be recommended. Pigs fed in the sties must not be given too large a quantity of acorns, especially at the beginning of the fattening period. The ration should be completed by green fodder, rich in nitrogen and water. The acorns should be crushed and mixed with other very laxative foods such as tuber or root plants, beet slices and fairly concentrated foods, such as bran. Cooking the acorns or meal made from them may diminish their astringency.

*Quantity of acorns which may be eaten by animals accustomed to them in their daily rations.*

Horses . . . . .	9.7 lbs. of fresh acorns	6.16 lbs. of dried acorns.
Dairy cows . . . . .	9.9 " " " "	6.16 " " " "
Beef or draught oxen	13.2 " " " "	8.14 " " " "
Pigs . . . . .	3.3 " " " "	2.2 " " " "
Sheep and goats . .	1.65 " " " "	1.1 " " " "

If only a limited quantity of acorns is available, it is best to keep them for the pigs because, so long as the precautions given above are observed, they have no bad influence on the meat, except on the fat.

It is advisable to use dried acorns without the cups, which are richest in injurious elements.

II. *Beechnuts*. — They have a fairly high food content and are very digestible. As the seed contains a poison, *fagine*, it must only be included

(1) On the use of acorns in distilling, see No. 94 of this *Review*. (Ed.)

in the ration of animals to a limited extent. On the other hand, horses may eat  $6\frac{1}{2}$  lbs. of them a day without any ill effects. Beechnuts, like acorns, should be given to pigs by preference. Although they have not the energy value of acorns, beechnuts are a food for cattle which should not be ignored.

67 — **The Pulpy Mesocarp of the Fruit of *Ricinodendron Rautaneii* as a Cattle Food.** — See No. 5 of this *Review*.

68 — **The Value of Cider Apples, Perry Pears, and their Respective Pomace as Food for Farm Stock.** — I. BARKER, B. T. P. and GIMMINGHAM, C. T., The Use of Pressed Apple Pomace, in *The Journal of the Board of Agriculture*, Vol. XXII, No. 9, pp. 851-858, London, December, 1915. — II. BARKER, B. T., and WALE, B. N., The Value of Cider Apples and Pomace as Food for Farm Stock. *Ibid.*, Vol. XXIV, No. 5, pp. 530-539, August, 1917.

I. — The writers apply the term pomace to the pulp of apples and pears in the condition in which it comes from the press after the juice has been extracted.

The total acreage in Great Britain under cider and perry fruit trees is approximately 100 000 acres; this corresponds to a total annual yield of 27 500 000 gal. or 183 333 to 220 000 tons of fruit, or 55 000-60 000 tons of pressed pomace. The total crop of cider fruit is probably not less than 200 000-250 000 tons, representing a yield of 60 000-75 000 tons of pomace.

Table I gives the results of the analyses of cider pomace carried out by the writers at the Agricultural and Horticultural Research Station of the University of Bristol. For comparison, the composition of wet brewers' grains and of mangolds are also given. Speaking generally, apple pomace is of a distinctly higher feeding value than mangolds, but it falls below wet brewers' grains as regards the amount of protein, though it is richer in carbohydrates.

TABLE I. — *Percentage Composition of Pomace.*

	Mixed apples 1913	Mixed apples 1915	"Bell" apple 1915	Ponsford apple 1915	Cap of Liberty apple 1915	Pear 1915	Wet Brewers' grains	Mangolds (Medium)
Water . . . . .	74.10	76.05	68.39	75.39	75.37	65.52	76.2	88.0
Ether extract . . . . .	1.24	1.12	1.43	1.22	(1.20)	1.30	1.7	0.1
Protein . . . . .	1.82	1.53	1.03	1.54	1.33	1.50	5.1	1.2
Crude fibre . . . . .	5.14	4.42	6.52	5.75	4.30	7.86	5.1	0.9
Ash . . . . .	1.11	0.71	0.65	0.56	0.76	0.92	1.2	1.1
Carbohydrates . . . . .	16.69	16.17	21.98	15.54	17.04	22.90	10.6	8.7

WARCOLLIER, in his book "Pomologie et Ciderie", quoting from WOLFFS' tables, gives for apple pomace a content of digestible nutrients of about: 1 per cent. of protein; 12 per cent. fat; 12.5 per cent. carbohydrates; nutritive ratio about 1:16.

In cider-producing countries, pomace is fed to stock when it is fresh;

if not given in large quantities (which would be injurious, especially in the case of dairy cows), no bad results are to be apprehended. Pomace, however, undergoes a rapid acid fermentation in addition to putrefaction. The best method of preserving it is by making it into silage. The silo may be improvised by using tubs or vats, or it may be specially constructed out of masonry, or dug out in the earth, the bottom and sides being covered with layers of straw. In some of the larger cider factories, pomace-drying plants have recently been installed. The product is sold to feeding-stuff manufacturers, and employed in making compound cakes or poultry foods. When for any reason, apple pomace cannot be used for food, it may be turned into a very good manure. Ordinary samples contain from 0.2-0.6 per cent. of potash; 0.4-0.7 per cent. of phosphoric acid; 1.6 to 1.7 per cent. of nitrogen, so that pomace is richer in manurial constituents than farmyard manure, but to neutralise its acidity, it should be mixed with bone or mineral phosphates.

Pomace can also be employed for making "small" cider, or low-grade cider, as well as for vinegar production or for cider and perry brandy.

II. — Description of experiments made in 1916, with pigs at the Seale-Hayne college, Newton Abbot, in conjunction with the Agricultural and Horticultural Research Station at Long Ashton, in order to determine the effect of substituting apples, or pomace, for a portion of a daily ration consisting of : sharps, maize meal, and fish meal. The quantity of apples given was gradually increased to from  $\frac{1}{3}$  to  $\frac{1}{2}$  and the pomace till it constituted from  $\frac{1}{10}$  to  $\frac{1}{3}$  of the total weight of the ration.

The percentage composition of the apples and pomace is given in Table II.

TABLE II. — *Percentage composition of Apples and Pomace.*

	Apples		Pomace	
	Sample 1	Sample 2	Sample 1	Sample 2
Water . . . . .	83.8	83.0	67.20	71.75
Protein . . . . .	0.7	0.5	1.90	1.70
Fat . . . . .	0.4	0.3	1.47	1.05
Crude fibre . . . . .	1.2	2.6	13.70	12.22
Carbohydrates . . . . .	13.3	13.2	15.17	11.78
Ash . . . . .	0.6	0.4	0.56	1.50

The experiment was divided into 2 periods: 1) from 5th. October to 15th. December during which both apples and pomace were used; 2) from 16th. December to 15th. January, during which only pomace was used. The results obtained at the end of each period are given in Tables III and IV. Each group contained 5 animals.

These Tables show that: 1) for fattening pigs of 55 to 60 lbs. per head, neither cider apples nor pomace give as satisfactory results as maize meal

and fish meal; 2) both apples and apple pomace possess a distinct feeding value for older, and store, pigs.

## BREEDING

69 — **Inheritance of Coat Colour in Swine: Experiments in the United States.** — SEVERSON, B., O., in *The Journal of Heredity*, Vol. VIII, No. 8., pp. 379-381, 1 fig. Washington, August, 1917.

The Mendelian principles of unit characters, dominance, and segregation appear to manifest themselves in the colour characters of pigs. SMITH (Colour Inheritance in Swine, in the *American Breeder's Magazine*, Vol. IV, p. 113) has shown that in the case of a Yorkshire crossed with a Berkshire, or with a Poland China: 1) white was dominant as regards black in the  $F_1$  generation; 2) in the  $F_2$ , the colours showed a general tendency to the separate manifestation of the original parental colours, in the ratio of 3 dominants: 1 recessive; 3) in almost every case, the black recessive of the  $F_2$  was accompanied by much more white than was present in the black parents. This suggests the idea that several chromosome factors, rather than a single one, are required for each colour. A. I. SIMPSON and J. P. SIMPSON (Analytical Hybridization, *Proceedings of the American Breeders' Association*, Vol. VII, p. 266), in a study on the crossing of different breeds of swine, state that: "The exact application of Mendel's law to all hybrid pigs in those cases where the original animals had been proved to be pure-bred and homozygous, and the resemblance between the pre-fertilisation chromosome reduction processes in animals and sexual plants,

leads us to conclude that all pure-bred swine fully obey Mendel's law, and that, if in crossing, a marked deviation occurs, this is positive proof of contamination in the case of one, or both, subjects".

In the experiments carried out at the Pennsylvania State College the writer observed the following facts: In the spring of 1915 were born a litter of young pigs, the offspring of a Berkshire sow, Dora XVIII of Penn. State 199 330 and a Duroc Jersey boar, Fancy King 58 875. Of the young pigs, 6 were red, spotted with black, and one black spotted with white. In the spring of 1917, another litter, produced by mating a pure-bred Duroc Jersey boar with a pure-bred Berkshire sow, contained 5 young pigs, of which 4 were red spotted with black, while 1 was black with the white spots of the Berkshire. The appearance in the 1st. generation of a black animal spotted with white had never been observed in any of the practical experiments at the above-mentioned College.

The case being an exceptional one, this black and white female of the  $F_1$  (1915) was chosen with one of its sisters from the same litter, and which showed the usual black and red coloration, for use in further experiments. As regards the case of the black and white pig born in 1917, the factors of heredity have not yet been investigated.

The hybrid white and black sow, born in 1915, was called No. I, and its sister No. II. These sows ( $F_1$ ) were both mated at the age of 1 year with a pure-bred Berkshire boar, Rival's Duke XXII 193 411, with the object of determining if the black and white sow No. I possessed any hereditary factor for red; sow No. II was used as a control.

### *Results of Mating.*

Parents		Colour of offspring (numbers of cases)			
Boar	Sow	Red and black	Black and white	Red, black and white	Yellow and black
$F_1$ — Duroc Jersey 38875	Berkshire 199330	6	1	—	—
$F_2$ — Berkshire 193411	Hybrid No. I	1	5	2	1
$F_2$ — Berkshire 193411	Hybrid No. II	6	4	4	—

The litter produced by mating the hybrid sow No. I (black and white) with a Berkshire boar showed a greater variation than that given in the above Table. At the end of the summer of 1915, the white hair of this sow became yellowish, as is usual in the case of white pigs, but in the winter, it again became pure white. At the age of 1 year, however, a narrow yellowish band appeared between the ears, extending down the back of the neck for from 4 to 6 inches. In the litter of 5 pigs which are described as black and white, one alone could be termed pure black with white spots. The others had reddish hair round the groin. One pig only was red and black, and in this case, the black was dominant, with patches of red bristles. The predominance of black as regards red in  $F_1$  had never been observed by the writer in the  $F_1$  of a Berkshire  $\times$  Duroc Jersey cross.

The usual arrangement of the colour of  $F_1$  did not appear in the 2nd generation when sow No. I was mated with a Berkshire boar. One pig was light brownish-yellow spotted with black. Two pigs showed distinctly the 3 colours black, red, and white. One of these had a black body with irregular patches of red and white. The other animal had 5 longitudinal bands of reddish bristles on a black body spotted with white. The last case is interesting, because young wild boars have longitudinal stripes on their bodies. This would seem to be an exception to the fact observed by CASTLE (*Genetics and Eugenics*, p. 137), who says that the character of stripes would appear to have disappeared in all domestic races of pigs, which are exclusively black, pink or white, or else black spotted with white, or red spotted with white. The only explanation of these longitudinal bands on the body would seem to be, that the determinants of their heredity are not entirely eliminated by improved breeds of pigs.

Given that in the litter produced by sow No. I, eight out of nine of the young pigs showed red, or traces of red, coloration, it is evident that this sow possessed a chromosome character for the colour red. It has been stated that in Berkshire pigs red is hereditary, but it does not seem reasonable to conclude from this case that sow No I did not possess the factors for the 3 colours black, white and red.

A litter of 10 pigs were obtained from the mating of sow No. II with the same Berkshire boar. The sow had a red body spotted with black. She also changed considerably in colour when over 1 year old; the red bristles on the abdomen and face becoming a pale yellow. The colour of the litter of sow No. II was more uniform than that of the young of No. I; 2 of the pigs being red spotted with black — 4, black spotted with white — 4, reddish black with white spots. There appeared to be a reversion in the colour dominance in the cases of sows I and II. In the first, black replaced red, as the ordinary fundamental colour, and white spots took the place of the usual black ones of the cross Berkshire  $\times$  Duroc Jersey. In sow No. II, which was of the usual fundamental colour, red with black spots, the white colouration was recessive or inhibited by some other factor. In the case of sow No. I, the factor for the longitudinal bands on the body, which are found in the wild boar, may have prevented the expression of its red factor. The fact that this sow had a narrow red stripe on the back of the neck, leads us to suspect that this may have been the case.

*Colouration in the other crosses.* — The following are the observations made by the writer as regards the colour obtained in the  $F_1$  by crossing the different breeds.

- 1) Berkshire  $\times$  Tamworth: Red (darker than in Duroc Jersey) spotted with black.
- 2) Berkshire  $\times$  Duroc Jersey: Red (of various shades) with black spots. Black (rare) with white spots
- 3) Berkshire  $\times$  Yorkshire: White (uniform) — White with black spots (rare).
- 4) Yorkshire  $\times$  Tamworth: White (uniform) with reddish shade.
- 5) Yorkshire  $\times$  Duroc Jersey: White (uniform) with reddish shade.
- 6) Berkshire  $\times$  Chester White: White (uniform) — White spotted with black (large proportion).

These observations do not confirm the general opinion that the uniform white of the Yorkshire breed is completely dominant as regards the red of the Tamworth and Duroc Jersey breeds.

70 — **The "Beirão" Horse in Portugal.** — MONTEVIO, ANASTACIO, in the *Revista de Medicina Veterinaria*, Year 16, No. 186, pp. 166-169. Lisbon, August, 1917.

HORSES

The breeding of "beirão" horses was fairly well developed in 1870; at that period, although retrograde, the breed was still plentiful on the Lisbon market, where it provided nearly all the cab-horses. Afterwards, the "beirão" horse quickly gave place to mule-breeding, and, in 1886, it was only bred in the plateau of Cõa.

All the Portuguese horses have the same origin, differences between the various breeds being due to different environment, attention, etc.

The "beirão" horse may be distinguished from the related breeds in southern Portugal by: its small frame, rarely more than 5 feet high; a heavy fleshy head; badly placed and rather thick ears; squat shape; somewhat coarse hair; very crooked hind joints; a coat where dark colours predominate. Those bred on the plateau of Cõa, where they are better looked after, are better, being more stylish.

The "beirão" horse forms a breed zootechnically distinct owing its origin to the special environmental conditions, such as: being bred in a granitic, mountainous, uneven region with the temperature varying round 0° C or still lower during more than half the year; total absence of the most simple care and attention, etc.

71 — **Milking by Machinery.** — HOPFER, J. J. and NUTTER T. W., in *The Field Illustrated*, Vol. XXVII, No. 10, pp. 755, 806, 810 and 812. New York, October, 1917.

CATTLE

Since 1913, at the Kentucky Experiment Station, 30 cows a day are milked by machine. Occasionally, when through some accident to the motor, it is necessary to milk by hand, 2 men can milk the herd in 1  $\frac{1}{4}$  hours, but more usually they need 1  $\frac{1}{2}$  hours, or 3 hours a day for the two milkings. With a machine the work can be done in 45 minutes, or 1  $\frac{1}{2}$  hours a day, but washing and attending to the apparatus before and after milking require another 1  $\frac{1}{2}$  hours. An expert workman can milk by hand as quickly as the machine, which takes 4 minutes to milk a cow, but, with the machine, two cows can be milked at once, and the milkers prefer the machine.

Mechanical milking is advantageous with a herd of 30 cows, and the larger the herd, the more necessary it becomes. With a herd smaller than 30 there is less to be gained by the use of a machine.

The four machines at the Kentucky Experiment Station cost \$568; in four years, repairs and new rubber parts have cost about \$448. The electric power used costs about \$3.90 a month or \$1.56 per cow annually. The combined cost of repairs for the machine and for power amount to \$5.31 per cow per year. Possibly a small gasoline engine would decrease the expense.

From data obtained from the Station and from the Elmendorf dairy, where 400 cows are kept, it was seen that the lactation period was extended from 11 to 16 months. Frequently mechanical milking was replaced by

hand milking during 1 or 2 weeks, during which little or no change was noticed in the milk flow. It should be noted that, unless the cows are carefully stripped by hand after machine milking, they dry off very rapidly.

By hand stripping a small quantity of milk, varying from half a teacupful to half a pint, is obtained. Hand stripping has the advantage of allowing the condition of the teats to be observed; it is carried out while the machine is milking another cow. To obtain perfect results the machine must work perfectly, faulty pressure may do harm, and the presence of blood in the milk may be attributed to it, but it is easily remedied. During 4 years only 5 cows were found which did not take to mechanical milking.

As many as 5 % of the cows in a herd may not be satisfactorily milked with a machine, but the other 95 % are accustomed to it after 2 or 3 milkings. Milk was obtained with as few as 50 to 100 bacteria per cc., and the bacterial count rarely exceeded 2 000 to 4 000. The average bacterial count of station milk published by the Lexington Health Board for July was 500.

The machines are cleaned with warm water, washing powder and a hard brush. The detachable parts are then rinsed and placed in an anti-septic solution. Just before milking, the teat cups and tubes are washed with water. Vigilance and care in cleanliness are absolutely essential both in machine and in hand milking.

The advantages of mechanical milking may be summarised as follows: it makes the work easier and the workmen are better satisfied. It does not decrease the amount of labour required, but makes it less hard.

#### POULTRY

72 - **Poultry Feeding Tests in New Zealand.** — BROWN, F. C., in *New Zealand Department of Agriculture, Industries and Commerce, The Journal of Agriculture*, Vol. XIV, No. 6, pp. 464-468, 1 fig. Wellington, June 20, 1917.

With a view to finding a substitute for wheat, which hitherto had been generally considered as an indispensable item of a laying fowl's diet, the New Zealand Department of Agriculture, in May 1915, instituted feeding tests at its Milton Poultry Station. The object of these tests was not to aim at high egg records, or high profits over the cost of production, but to ascertain, as far as possible, what results could be obtained by the elimination of wheat from the ration.

The offals of wheat, pollards and bran were included in the dietary.

The 1st. year's tests lasted from May 1, 1915 to April 28, 1916; 4 pens each containing 6 fowls took part: 2 of white Leghorns (pens 1 and 3), and 2 of Brown Leghorns (pens 2 and 4). One pen of each breed had wheat in the ration and the others none.

The 2nd. year's tests commenced on May 1, 1916 and concluded on April 30, 1917. Pens 1 and 3 received the same dietary as in the preceding year; in the case of pens 2 and 4, the only alteration was that lucerne-meal was substituted for pollard. It is interesting to observe that the leading pen, No. 4, received no pollard or wheat.

*Conclusions.* — Wheat and even pollard, are not indispensable in the dietary of the heavy layer when oats and lucerne-meal are both substituted.

Hens in their 2nd year, with both wheat and pollard eliminated from the ration, can produce a profitable number of eggs; meat-and-bone meal

makes a good substitute for boiled meat. The quantity of meat-meal eaten is largely influenced by the number of eggs laid. This is indicated by the quantity of meat-meal consumed by pen 4 (See Table).

A large quantity of meat-meal can be consumed by heavy-laying stock without injurious effects such as ovarian troubles, provided the meal is chiefly supplied in a separate hopper and kept always before the birds for them to pick at.

Lucerne-meal is preferable to the chaff-hay form of lucerne as an egg-producer, and also as a labour-saver, steaming over night being unnecessary.

73 — **Turkey Rearing in Italy.** — CASTELLARI, A., in the *Gazzetta Agricola, Commerciale e Industriale, Organo del Consorzio delle Cattoliche Ambulanti di Agricoltura per la Provincia d'Alessandria*, Year 1, No. 21, pp. 141-142. Alexandria, Italy, November 15, 1917.

Among the chief breeds of turkey (Norfolk black, Cambridge buff, common black, English white, bronze), the best is the bronze, especially for its early maturity and weight producing qualities (on an average 35 lbs. for the mature, and 24 lbs. for the young turkey, cock; 25 lbs. for the mature hen and 15 for the young hen). Crosses have been made, particularly at Ravenna, between the white English breed (delicate flesh, but not so hardy as the common black) and the common breed, and excellent results have been obtained. The common turkey hen produces about 40 eggs a year if she sits; if she does not, double the number may be laid. The hen can do three successive sittings of 30 days each without any harm if given abundant food; according to her size she can sit 20 to 24 eggs, so that in 90 days, from 60 to 70 turkey-chicks would be obtained per turkey-hen.

The writer gives the following rules for feeding:

No food to be given for the first 48 hours after hatching.

First food: bread (even of maize) soaked in skim milk, mixed with 1 hard egg for 5 chicks and a finely chopped onion.

Ten days after hatching, flour mash (maize, rye, etc.) mixed with finely chopped chicory, nettle and onions.

At about 1 month, a pinch of pepper should be added to the mash.

At 2 months, always give cooked food, divided among 4 meals a day; later, 2 meals will suffice.

During the critical period in rearing turkeys, seeds of hemp, flax, millet, rye, oats, wheat, *well cooked*, should be preferred, as well as stale bread and waste meat; add a little pepper and chopped onion.

In fine weather, the flock should be sent to pasture.

During fattening, which begins a month before sale, the time spent out at pasture must be decreased, and well varied food given, always cooked and salted; thus, give mash in the morning and grain in the evening (oats are very good).

The following daily rations suffice for 20 turkey chicks; the total cost of the first 2 is about 2½d.; that of the 3rd about 2d.; they are most suited for seasons when other fresh food is lacking.

I. — Maize flour, 4 parts; sesame cake, 4 parts; Oats, 2 parts (cooked and salted); ~~and~~ weight, 2.2 lbs.

II. — Cooked potatoes, 8 parts; sesame cake, 4 parts; rye, 3 parts (cooked and salted):  
— *total weight*, 3.2 lbs.

III. — Kitchen waste, cooked potatoes, 6 parts; maize flour, 4 parts (cooked and salted):  
— *total weight*, 2.2 lbs.

The common breed, when suitably fattened, will reach the following weights: male, 20 to 22 lbs.; female, 11 to 13 lbs. An 11 lb. turkey-hen will give: 62.5 % of meat; 8.5 % of bone; 4 % of fat; 6 % of feathers; 19 % of blood, viscera, etc. Turkey flesh contains, on an average: 55 % of water; 20.6 % of nitrogenous matter; 22.9 % of fat; 1 % of ash.

Three hens and a cock were kept by a small household; 120 turkey-chicks were hatched, of which 90 lived and were reared.

The accounts were made up as follows:

## EXPENSES.

Upkeep of 3 hens . . . . .	19 s.
Upkeep of 1 male . . . . .	6 s. 5 d.
Upkeep of the chicks for the first 3 months . . . .	120 s.
Cost of guarding while at pasture . . . . .	60 s.
Cost of fattening, at 1s. 2 $\frac{1}{4}$ d per head . . . . .	109 s.
<i>Total Expenses</i> . . . . .	313 s. 5 d.

## RECEIPTS

90 turkeys, averaging 15 lb. each, i. e. 1350 lbs. at 13.4 d. per lb. . . . .	1824 s. 2 d.
Manure produced at 9 $\frac{1}{2}$ d. per head . . . . .	71 s. 3 d.
<i>Total receipts</i> . . . . .	1895 s. 5 d.
<i>Total profit</i> 182 s. or £ 189 2 s.	

74 — **Transmission of Richness in Silk and Hardiness in Crossing Silkworms.** — GRANGEON, E., in *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. 3, pp. 888-891. Paris, October 10, 1917.

SERICULTURE

The author (ex-director of the sericultural Station of Nanisana, Madagascar) points out that, in tropical countries, it is essential to rear hardy breeds, as the methods of the natives are not sufficiently careful and larvae of all ages have to eat a mixture of young and old mulberry leaves, owing to the method by which the tree is cultivated. They also have to bear a very high temperature and a moist atmosphere.

There are very hardy breeds, especially in Bengal, but the larvae, which are quite small, only give a cocoon with a very thin covering of silk.

It seems impossible to combine the two characters *hardiness and richness in silk*. In Bengal very clear results were obtained on the transmission of these characters to the products obtained by crossing native breeds with improved European and Madagascar breeds.

In all the crossings the silk-worms of the 1st. generation distinctly have the hardiness of the mother and those of the 2nd. and 3rd. generations a hardiness intermediary to that of the father and that of the mother. The larvae of the following generations gradually divide up into small, resistant larvae and large larvae with but a slight resistance which die out.

In all the crossings the larvae of the 1st. generation have the richness

in silk (if anything slightly increased) of the parent, male or female, which is richest in silk. Those of the 2nd. and 3rd. generation have a richness in silk rather inferior to that of the 1st. generation, then individuals rich in silk gradually die out in the following generations. The dying out of these worms is caused by the climate and does not occur if the crossings are made at such an altitude as to attenuate the effects of the climate.

These facts show that crossing a Bengalese female with a male of improved breed would give, in the first generation, silkworms having the hardness of the Bengal breeds and the richness in silk of the European ones. Cocoons rich in silk would thus be obtained in a climate fatal to improved breeds. The two following generations might also give satisfactory results during a good part of the year.

The difficulty is to obtain, at the requisite moment, males of improved breeds, which must be kept pure. Moreover, if the larvae hatch out well in the first generation, it is a different matter in the following generations when a polyvoltin is crossed with a monovoltin. All these difficulties may be overcome if there is a mountainous district near enough, which does not require a journey of from 10 to 12 days (as is the case in Madagascar). In the mountains of tropical countries where the altitude is sufficient to make the climate temperate it is easy to obtain improved polyvoltin breeds throughout the year. Moreover these breeds may always be obtained by crossings (followed by selection) between European monovoltins and polyvoltins of tropical countries.

**75 - The Appearance of "Accidental Bivoltins" in Univoltine Breeds of the Silk-worm.** — LÉCAILLON, A.: I. On the Appearance of "Accidental Bivoltins" in Univoltin Breeds of the Silkworm and the Explanation of this Phenomenon, in *Comptes Rendus des Séances de l'Académie des Sciences*, Vol. CLXV, No. 18, p. 603-605. Paris, Oct. 29, 1917. — II. On the Special Characters Shown, at Various Stages of their Development, by "Accidental Bivoltins" appearing in the Mulberry *Bombyx*. *Ibid.*, No. 20, p. 683-685. Nov. 12, 1917.

I. — "Accidental bivoltins" are 2nd. generation silkworms sometimes found among univoltin breeds. The author gives the following results of the observations and experiments he has carried out on this supplementary generation, observed for a long time by breeders:

1) In 1917, the univoltin breed, studied since 1914, gave 3 cases of bivoltism.

The first was that of the pair which matured earliest, and appeared on June 18. The fertilised eggs of this pair began to hatch 10 days after being laid (a fact which, normally, should only occur after 9 ½ months). About 400 eggs were laid by the female, 377 of which produced larvae and a few only remained at the customary stage of normal univoltin eggs which hibernate; 10 larvae died in the eggs.

Two other females, born on June 21 and 27, whose copulation was prevented, laid eggs, some of which produced, a few days after being laid, larvae which died as soon as they hatched (1).

(1) On the subject of pathogenesis in the silkworm, see R. October, 1917, No. 936, and R. November, 1917, No. 1050. (Ed.)

2) In order to see whether temperature could cause bivoltinism, experiments were made in which the cocoons, then the moths and eggs, of a univoltin breed were placed in a special room, the temperature of which was always kept at 25 to 30° C., *i. e.*, some degrees higher than that at which the eggs are usually laid. There were no bivoltins.

3) It seems that the appearance of bivoltins may be explained as follows:

a) The embryos, larvae, chrysalides, and moths from different eggs laid by the same female mated with a single male are far from being identical either from a morphological or physiological point of view. The time required by the embryos to form within the egg especially, is very inconstant. The remarkable difference between various individuals of the same parents is due to the fact that the ovules of a single female are no more identical with each other than are the spermatozoa of a single male.

b) Direct action of environment is not the determining cause of accidental bivoltinism.

c) It is known that the action of cold, high temperature, brushing, electricity, and acids will cause ordinary univoltin eggs to hatch prematurely. In the production of accidental bivoltins, however, it is only a question of the direct and prolonged influence of the breeding conditions which acts on the composition of the eggs which are being formed, and doubtless also, on the developing spermatozooids.

d) In the author's experiments, the eggs kept for reproduction remain, during the first 3 months after being laid, at a temperature which is often as high as 30° C. During winter the temperature is not below 5 or 6°. It is probable that, under these conditions, the univoltin embryos are so influenced that those which already have the capacity of transforming rather quicker than the others, have this tendency accentuated. From them are descended, in the following spring, moths whose progeny is more or less entirely accidentally bivoltin.

Finally, the author points out that this phenomenon must be gradually more marked in rearing if, from year to year, the moths which appear first are used for breeding.

II. — "Accidental bivoltins" seem to represent an important step in the scale of the changes that a univoltin breed may undergo to form a well defined bivoltin one, and, in order to help comprehension of the variations produced in the species during centuries of rearing under different climates and which may still be produced, the author gives the special characters of the bivoltins appearing in his rearings at all the stages of their development.

a) The eggs of the 3 layings where the author observed cases of accidental bivoltinism were so poor in yellow colouring matter that they appeared almost completely white. Their chemical composition was, therefore, different from that of ordinary univoltin eggs. Consequently, the conditions of rearing, when they cause the production of accidental bivoltins, first cause changes in the chemical composition of the egg, particularly of the vitellus.

b) During the embryonic development of the accidental bivoltins, the colouration of the egg changes only slightly, owing to the small amount of colouring matter present.

c) Contrary to the general belief, the author is of the opinion that most accidental bivoltins can be easily reared, breeding being normal, and that these larvae are no more subject than ordinary univoltins to the diseases, etc., that commonly attack *Bombyx*.

d) The author has noticed no particular difference between accidental bivoltins and normal univoltins in their other stages, *i. e.*, as chrysalis and perfect insect. Copulation and oviposition were quite normal; the number of eggs laid by accidental bivoltin females corresponds with that laid by ordinary univoltins.

76 - **Methods of Identifying Silkworm Eggs Made Bivoltin by the Action of Hydrochloric Acid; Investigations in Italy.** — ACQUA, C, in *Rendiconti dell' Istituto bacologico della R. Scuola di Agricoltura in Portici*, Vol. II, pp. 75-77 Portici, 1917.

Of recent years there has been a large demand for silkworm eggs for the summer-autumn rearing. Among the treatments to which the eggs are subjected to make them hatch prematurely are immersion in a suitable dilution of hydrochloric acid and exposure to "electric rain". It sometimes happens that there are put on the market eggs said to have been treated electrically which, in reality, have only been subjected to the hydrochloric acid bath. The deception may be discovered by the following characters of eggs treated with hydrochloric acid:

1) Dark brick-red colour inclining to a violet, almost wine, shade; the eggs remain this colour till just before they hatch, when they turn pale, finally becoming the same colour as ordinary eggs.

2) Complete removal of the sticky layer which envelops the eggs in the natural state and enables them to adhere to objects and each other, Silkworm eggs treated with hydrochloric acid are not sticky and may easily be run through a narrow funnel.

These characters are common both to the native yellow and Chinese breeds and to crosses between them.

Eggs treated electrically do not change colour, but only become a little less dark and their colour is indistinguishable from that of other eggs with which they are compared. There is no effect on the sticky layer.

77 - **"Akino-nogeshi" (*Lactuca brevirostris*), A New Silkworm Food Recently Discovered in Japan.** — *Le Moniteur des Soies*, Year 55, No. 4870, p. 2. Lyons, December 8, 1917.

Mr. FUJIMA DAIJIRO (chief of the Oi branch of the Silkworm Institute of the Gifu Prefecture) has recently discovered that a plant "akino-nogeshi" (*Lactuca brevirostris* Champ.), is probably not inferior to the mulberry in silkworm feeding. He obtained excellent results with this food; larvae fed on it from the first stages gave, if anything, better cocoons than those fed on mulberry leaves. This discovery is of great value in districts where frosts injure the mulberry trees. As the plant in question is hardy and wild, it can be left to grow in the mountains or plains without any special care being given it.

78 - **Carp-Breeding in Transplanted Rice Fields: Experiments at Vercelli, Italy (1).** — MARCARELLI, B., in *Il Giornale di Riscoltura*, Year VII, No 19-20, pp 218-253. Vercelli, October 15 and 30, 1917.

FISH CULTURE

It is especially due to the "Società vercellese di agricoltura" that, for some 3 years, carp breeding is spreading in the rice fields of the province of Vercelli. Although this new industry has not yet passed the experimental period, yet it has given very encouraging results. It should be remembered that, besides its value, the carp is an excellent help in combatting malaria, and destroying weeds by eating their seeds (Prof. SUPINO has found seeds of *Glyceria Polygonum*, *Cyperus* and *Chara*, etc., in the intestine of the carp), as well as hindering their germination by agitating the surface of the soil.

The rice-growing Station of Vercelli has done much propaganda work for rice-growing by transplanting (2); this is why the Station advocated the trial of carp-breeding in transplanted rice-fields. Towards the end of June, 1917, mirror-carp fry, from Galicia, were placed in two plots of the Station's experimental field, each plot measuring about 6000 sq. yds. On July 11, 180 small carp, each weighing from 16 to 19 gm. were added to the fry in one of the plots. Nothing further was done, save to regulate the water supply. On August 26, the water was drained from the rice fields and, 2 days after, the fish were collected and found to weigh from 150 to 180 gm. for the fry and 300 gm. for the small carp. The fish were put in a pond for the winter.

The writer concludes from these results that carp breeding in transplanted rice fields is possible if fry or young fish of 1 or 2 summers are used. On the other hand, the use of mature fish cannot be advised, seeing that the season is too far advanced when the water has to be run into the rice fields (about mid-June). In comparison with the directly-sown rice field, the transplanted rice field offers the following advantages: — freer and quicker circulation for the fish, giving easier feeding and quicker growth; the possibility of always keeping a constant supply of water; greater saving of special work such as ditching, etc. The presence of carp in the transplanted rice field causes no damage whatever, especially if the precaution is taken, when small carp of 1 or 2 years are used, of not putting in the fish till 10 or 12 days after transplanting, that is, when the plant is well rooted.

79 - **The Amazon Turtle as a Producer of Eggs, Meat and Fat.** — TAVARES, J. S., in *Boletim, Serie de Publicação Cientifico*, Vol. XV, Part. VI, pp. 279-283, fig. 2. Braga, November, 1917.

OTHER LIVE STOCK

Turtles are extraordinarily abundant in the Amazon and its tributaries. The true turtle (*Podocnemis expansa*) is adult at about 10 years old; it is then about a yard long; the dorsal carapace will measure about 31 inches, while the body weighs from 26 to 33 lbs. As the carapace has no horny scales, like those of the marine turtles, it is of no commercial importance. The eggs and meat are utilised, however.

(1) See also: F. SUPINO, *Carp-Breeding in Rice Fields in Italy*. B., September, 1913, pp. 1332-1335. — (2) See B., 1915, No. 271. (*Id.*)

At the egg-laying season, the turtles appear in hundreds on the banks of the river and dig pits about a foot deep and 2 to 3 ft. wide, in which, after about a fortnight, from 60 to 140 white and almost spherical eggs are laid. The females fill up the holes with earth, which they afterwards smooth over to hide the place. Incubation is by the heat of the sun; shortly the young turtles appear and enter the water in search of food.

The natives ("caboclos") hunt for eggs, testing the ground with a stake, until a hollow sound is obtained. The eggs are equally eatable whether raw or cooked. By a very crude process, the natives extract a fat called "turtle butter" from the eggs, to use as food or for burning. The fat is sold in tins of about 40 lbs. at an average price of 11 milreis (24s. 8d. at par). The turtle butter is mostly prepared in the regions of Upper Amazon, Jurna, Tefé, Rio Negro, Purus, Yutahy, Madeira, Solunões and Javary; thousands of pound's weight are sent every year to the market at Belem de Para.

Tortoise meat forms a great part of the food of the poorer classes; that of young animals is more appreciated, thus costing more. Living turtles are often sent to Europe, where the meat, particularly used for making soup, constitutes a very delicate dish.

The turtles are captured either by hand, by shooting with arrows, with hooks, or with nets.

When the turtles are wandering along the banks of the river at egg-laying time, the natives chase them and turn them on their backs. They are then quickly (10 to 15 minutes exposure to the sun suffices to kill them while on their backs) taken in canoes and kept alive in water, in enclosures called "currales" surrounded by stakes to prevent them from escaping. The turtles are kept thus until sold or eaten. The price of an adult turtle, formerly very low, now varies from 5 to 20 milreis (11s. 3d to 45s. at par). In addition to the true turtle (*Podocnemis expansa*), the natives on the riverbanks of the Amazon also hunt other Chelonians, such as; the "tracaja" (*Podocnemis du merihana*); the "kágado da matto" (*Rhinemys nasuta*); "jabuty machado" (*Platemys platycephala*); "jabuty aperema" (*Nictoria punctularia*); "matamata" (*Chelys fimbriata*); and the "mussuau" (*Cinosternum scorpioides*). very abundant in the island of Marajó.

## FARM ENGINEERING.

80 - The Tractor in Relation to the Farm and Its Machinery. — KRANICH, F. N. G., in the *Transactions of the American Society of Agricultural Engineers*, Vol. X, No. 2, pp. 101-108. Ames, Iowa, March, 1917.

According to the writer, there exist, between the tractor and its environment, relations of three types:

- 1) Relations to draft machines,
- 2) Relations to belt-power machines,
- 3) Relations to the economics of the farm

These factors are all equally important, but, unless the tractor's utility can be divided equally among them, it is not a success on the farm.

*Draft machines.* — Considering the actual horse power required, ploughing constitutes the heaviest work of farming, though not the longest in actual hours of work. Milking requires at least an hour morning and evening for one man, which totals to 73 days of 10 hours per year. Ploughing on the average farm requires less than 20 days per year. Farmers often consider tractors as merely ploughing machines; to this end the horse drawn gang ploughs have been adapted for use with tractors, as the other farm draft machines will probably be. The disc harrow, the spring tooth harrow, clod crusher, etc., are best used right behind the plough.

Most of these machines are usually drawn by 2, 3 or 4 horses; too much power would be wasted were they hitched alone to the tractor. Several of these machines should be combined, or one large machine should be constructed, to form a sufficient load for the tractor.

But it remains to be seen if that is desirable, for each binder or mower would require a man, so that the measure would defeat its usefulness. Moreover, the extra expense of these machines would cost too much per unit of production. Again, the small tractor is limited in power, and the size of farm for which it is suited would not require 2 or 3 binders, mowers, or harvesters. Drawing a manure spreader, a tedder or rake is ordinarily work for 2 horses. The tractor's relation to either of these machines is questionable. The tractor can, of course do this work, but is it economical? A spreader is empty half the time and then is not even a load for a 2-horse team. To draw 2 or 3 spreaders by a tractor might not be economical, on account of the time lost in loading, hitching and handling. Harrows, manure spreaders, etc., might be adapted to tractors, but it would increase the machinery cost to the farm, as well as necessitating changes to provide accommodation for them. Would this be considered economic farming, and would the method lower the cost of production? In the next few years, the tractor will certainly reach such a stage of development as to render it still more useful. Farm machines will be built in sizes to suit economical working of the tractor and they will be of better design and construction. The tractor does not need to replace all the farm horses, but it must replace some to prove its economic value. If the tractors replaces horses of value equal to twice its cost, it has served a great part of its intent.

*Belt-power Machines.* — The tractor should be able to drive the belt or power machines of the farm; but the tractor and the machines (grain separator, huller, saw, etc.) should be so arranged as to work at the maximum capacity consistent with efficiency. Convenient belting should be provided as well as proper speeds without unnecessary pulley-changing. A tractor suitable for belt work only would not be considered an economic farm machine. It is probable that few of the gas or steam tractors used in the United States represent a profitable investment for their owners, for they remain idle so much of the year, because belt work, primarily threshing, was their purpose.

It is the variety of things done economically by the tractor during the year that makes for its close relationship to the farm and its machinery. If belt work is the principal aim, the portable engine will solve the problem

at half the cost of a tractor, for most of the expense of the tractor lies in its transmission parts, which are for draft work.

*Farm Economics.* — The economic relation between the tractor and the farm in general is very important. Although closely related to the draft machines and power machines, the tractor may prove rather an expense than a saving, if it is not in proportion to the whole farm. Thus, an 80-acre dairy farm, with 5 horses, would obtain no economic advantage from the purchase of a 15-30 HP. tractor, which, although of first-class construction, would be more suited to a 600-acre farm.

The tractor will bring about a new era in farm machinery. Its value is only just beginning to be recognised. Farm machinery will be redesigned to meet the needs of tractor farming, as well as being constructed to give better and longer service. At present it is often of poor quality. It should work more efficiently, have a longer life, which would give better profit and reduce the unit cost of production.

81 — **Machine Cultivation Tests at Noisy-Le-Grand, France** (1). — RINGELMANN, MAX, in *Feuilles d'Informations du Ministère de l'Agriculture*, Year 22, Nos. 39 and 41, pp. 7-9 and 12-13, tables 7. Paris, September 25 and October 9, 1917.

The author's second report on the trials at Noisy-le-Grand (France) deals with 12 machines indicated in the appended Table, which summarises the results of the work carried out.

As a supplement to the special trials in 1913-1914, 1915, 1916 and 1917 (which concerned 63 machines) the writer formulated a number of conclusions, the chief of which are given below.

The weight of the tractors should not be more than 6160 to 6600 lbs.; such machines are easy to handle and give an average tractive effort of from 1320 to 1540 lbs. Above such a tractive effort, the machines do not last long, the axles are strained, thus resulting in greater wear and tear, with a reduced length of life.

When the work (breaking-up or deep ploughing) requires a tractive effort of more than 1320 to 1540 lbs., recourse should be had to a winch tractor.

To provide for good steering, about one-third of the total weight should be carried by the steering wheels and two thirds on the driving wheel or wheels. Two steering wheels are more effective than a single one.

The weight of the tractor in relation to the width of the wheels should not be more than 170 to 180 lbs. per in. of tyre width (figure obtained and checked at the trials). Neither the width of the tyres nor the diameter of the driving wheels (43 to 55 ins.) should be increased too much.

In the case of exterior transmission to the driving wheel or wheels (gears or chains) a clearance of at least 10 to 12 ins. should be left between the ground level and the lowest point of the drive or gear box.

A differential should be dispensed with, one driving wheel or 2 driving wheels placed close together being used instead. With one driving wheel working in the furrow and the other on the unploughed land, the strain falls

(1) The tractor towed, on freshly turned soil, a 48-tine harrow weighing 90 kg. — (2) Ploughing tests could not be carried out. — (3) The tractor towed a 13 flexible-tine harrow on the ploughed land. — (4) First machine built; no price yet fixed. — N B. The machine S is a double-brabant plough, on the fore part of which are fixed a small motor and two hauling winches.

constantly on one side of the differential, one of whose gears wears more quickly than the other.

As regards grips fixed to the driving wheels strakes of various forms damage the ground much less than grouts and other types of grip which tend to pack the soil.

The strakes should run on the unploughed ground; turning the last strip of ground destroys the compressed part, which does not take place when one of the driving wheels runs on the furrow-bottom; in this last case, the packed parts covered in ploughing remain unchanged in hard blocks; this difficulty does not occur in sandy soil. One driving wheel may run in the furrow, but it is inadvisable.

Motors of 20 to 25 HP., with several cylinders of the automobile type and running at high speed, are preferable.

The circulating pump should be gear-driven, while the fan should be driven by a belt.

Endless-track devices (caterpillar treads) should be avoided on account of the difficulty of steering and the rapid wear of the many articulations.

The front-bogie tractors act almost like motorploughs; steering the driving wheels is difficult on account of their weight on the soil, especially if one wheel, provided with grips, runs in the furrow. The steering of the wheelbarrow type of motor plough is also difficult.

The double-brabant windlass plough, which has been largely tested, is of interest for average cultivation.

With a pull of from 1320 to 1520 lbs., an average speed of 3250 yds. per hour seems suitable; the speed may be increased up to 4300 yds. per hour, but on further increasing it, steering becomes difficult and the traction of the implement becomes too heavy. Under similar conditions of work, period, soil, plough, the tractive effort increases from 100 to 118 when the speed increases from 1 to 2.5

The use of the tractor is best suited to furrow lengths of not less than 500 feet. The time required for turning is about  $\frac{1}{2}$  a minute (20 secs. with a good driver, 1 minute with an unexperienced man).

Two men are required: 1 mechanic on the tractor and an ordinary assistant on the implement being towed; this latter does not exclude automatic lifting.

More than 50 minutes of actual work per hour cannot be relied upon.

A traction buffer should be placed between the tractor and the implement being towed. In this way an economy of 33 to 54 % is gained on the starting-pull and 19 to 30 % on the average tractive effort, which only affects a part of the hourly consumption of the tractor while reducing the wear of the machinery.

It is worth while hitching a harrow to the plough for ploughing before autumn sowing and for that of spring.

The great advantage of the tractor, resulting from the area it can cover per hour, is that the farmer can immediately utilise the favourable opportunity for ploughing.

The tractor is used to best advantage on furrow lengths of from 3250 to 5000 ft., in fields with slopes of not more than 7 or 10 %.

Travelling by road should be reduced as far as possible, unless the grips are removed from the driving wheels, and other precautions taken.

**82 - Machine Cultivation Trials at Bourges, France, in 1917.** — DESSAISAIK, R., in the *Journal d'Agriculture Pratique*, Year 81, No. 23, p. 450. Paris, November 15, 1917.

The departmental Syndicate for machine cultivation of Cher has carried out ploughing tests with tractors in September 1917, near Bourges, France. M. E. RABATÉ, Director of agriculture for the department of Cher, noted the following results :

Tractor	HP.	Average depth of work, in cm.	Area ploughed per hour, in sq. metres	Petrol used per hectare, in litres	Cubic metres of earth turned per litre of petrol
Mogul. . . . .	16	17.2	2 614	23.30	73.8
Titan. . . . .	20	19.0	3 528	21.25	89.4
Case. . . . .	20	17.0	2 925	28.23	60.2
Avery. . . . .	16	18.5	1 707	21.15	87.1
Emerson. . . . .	20	18.0	2 604	32.90	54.7
Gray. . . . .	30	17.0	3 255	27.20	62.5
Moline. . . . .	12	17.0	2 092	29.00	58.6
Globe. . . . .	18	57.0	2 196	43.90	38.7

In these trials the furrow length varied between 728 and 998 ft.

The Case, Avery, Moline and Globe tractors each towed a 2-furrow plough ; the Mogul, Titan and Emerson tractors towed a 3-furrow plough ; while the Gray tractor towed a 4-furrow plough.

**83 - The Cost of Fuel used by Tractors for Ploughing, in Canada.** — ATWOOD, CHARLES A., in *The Canadian Thresherman and Farmer*, Vol. XXII, No. 10, p. 32. Winnipeg, Canada, October, 1917.

The writer has used a kerosene-burning tractor of 8-16 HP. on a 200-acre farm for all cultivation work and for working a hay-press and a chop-cutter.

The tractor worked 67 days during a period of 3 months ; the number of working hours was 403, or 6 hours a day.

The work was done on a heavy loam soil, where 3 ploughs are a maximum load for the tractor used (a small size one), and where, without a good operator, 2 ploughs could be handled to better advantage and less overload to the engine at moments of extra stress. The costs per acre are given below.

In the spring cultivation the tractor pulled two 8-ft. disc harrows and a 10-ft harrow.

To work an acre required 38 minutes, the cost for fuel and lubrication

tion being 18 ½ cents per acre. Very few repairs were necessary during the first year of operation.

Work.	Cost of fuel and lubricant per acre.	Time required per acre.
Spring ploughing (maize stubble) . . . . .	\$ 0.27	1 hr. 12 min.
» » » » (clover sod) . . . . .	\$ 0.31	1 hr. 24 min.
Early autumn ploughing (oats stubble) . . . .	\$ 0.27	1 hr. 9 min.
Late autumn ploughing (oats stubble) . . . .	\$ 0.30	1 hr. 11 min.
Late autumn ploughing (wet, maize stubble).	\$ 0.40	1 hr. 30 min.
December ploughing (clover sod) . . . . .	\$ 0.36	1 hr. 42 mins.

84 — The "Motoculteur", Built by the "Société La Motoculture Française". — FREMIER, VICTOR, in *Le Génie Rural*, Year 9, No. 69; New Series, No. 9, pp. 1-5, figs. 3. Paris, 1917.

The "Motoculteur" <sup>1</sup>(1), which took part in the Noisy-le-Grand trials, is the 30 HP. 1917 type embodying all the latest improvements.

The frame properly so-called is formed by what might be called the

Fig. 1. — The "Motoculteur" working while mounting a 14 % slope.

1) In the *Notes de Culture Mécanique* by DR. CHAUVÉAU (Librairie Bailière, Paris, 1917), there are described 4 types of "Motoculteurs" constructed by the Société LA MOTOCULTURE FRANÇAISE, Boulevard Hausmann 41, Paris. These types are: 1) Maraîcher; weight, 440 lbs.; 4-5 HP.; price, £ 80; 2) Vigneron, weight, 3 300 lbs.; 16 HP.; price, about £ 200; 3) for large scale work; weight, 4 400 lbs.; 30 HP.; price, £ 610; 4) for large scale work; weight, 5 060 lbs.; 40 HP.; price £ 600.

"belly" of the machine, which contains and protects the machinery working in a bath of oil. There is no external greaser. The total length of the machine is 13 feet, the width being 5 ft. 3 in. The machine (fig. 1) is carried on two driving wheels and a single steering wheel; it is very stable as the centre of gravity is very low, being situated a little forwards of the driving wheels. The latter are of 47 in. diameter, and are placed at a point  $\frac{2}{3}$  of the total length. The motor is 4 cycle, 4 cylinder and gives, at 1000 to 1250 revolutions, from 30 to 35 HP. (bore 90, stroke 170); it is provided with a governor. The carburettor includes an automatic air-filter; the fuel consumed is 0.4 litres per HP.-hour; the tank holds 60 litres. The magneto is enclosed and completely protected from dust. There is a friction coupling and 4 gears giving speeds of 15, 25, 36 and 59 inches per second respectively, as well as a reverse.

As is shown in fig. 2, the rotary apparatus of the "Motoculteur" is placed behind; there are 2 speeds (150 and 180 revs.) which allow of

Fig. 2. — Diagrammatic side-view of the "Motoculteur" showing the rotary apparatus.

regulating the work according to the soil and the type of tilth that is required. The transmission to the apparatus is by a central, universal joint drive.

The machine turns in its own length (in a circle with a radius of less than 10 ft.) and, having no differential, turns on the free interior driving-wheel. The machine guides itself when travelling in a straight line, so that the driver can descend from the machine, if necessary, and walk alongside to examine the work, etc. The 1917 type of "Motoculteur" can perform two functions: 1) by means of its extensible rotary apparatus, work the soil completely, producing a *uniform tilth over all the layer worked* in a single journey and in widths of from 59 to 71 ins.; 2) without its rotary apparatus, work as a tractor, towing all the usual farm implements, including multiple furrow ploughs or digging brabants.

The rotary apparatus, tearing at the soil in the direction of movement

can, even in a loose, damp soil, ascend with its ordinary wheels slopes of more than 15 %, when fully working.

On the other hand, when used as a tractor, removable strakes giving a good grip are provided for the driving wheels ; in addition, when its normal weight does not exceed 4000 lbs, extra weight can be given by means of sacks of earth or lead bars of 1100 to 2200 lbs. In this state the machine gives, in suitable ground, a draw-bar pull equal to 50 % of its total weight, or 1980 to 2640 lbs. The gears are designed for such strains.

Thanks to its lightness, the machine can work with its rotary apparatus in all fields, even on deeply ploughed land, with a single turn, and it can prepare such land for sowing much better than scarifiers and harrows. On solid land, the machine can produce a loose tilth of from 2 to 11 or 12 ins. deep, according to the speed at which it moves. This type, at any rate, is not designed for deeper work, but it can carry it out as a tractor by towing a digging brabant.

Fig. 3 — The "Motoculteur" working as a tractor

In normal soil of 110 to 132 lbs resistance, with a width of 1300 to 1625 feet, the machine is guaranteed to yield per hour of actual work (complete work and with a single turn of the rotary apparatus) as follows :

- 1) at least 1 800 sq yds at 9 to 12 ins deep (1st speed forward)
- 2) " " 3 000 " " " 7 to 10 " " (2nd speed forward)

- 3) at least 4 800 sq. yds. at 5 to 7 ins. deep (3rd. speed forward)
- 4) " " 7 200 " " " 2 to 3 " " (4th. speed forward) for hoeing, ploughing-up stubble.

In practice, deducting stoppages and the usual losses of time, the machine will perform : about 3.25 acres of hard digging-work, either loosened or brabant-style; about 6.25 acres of average work, tillage or ordinary ploughing with a 3-furrow plough ; about 15 acres of hoeing or ploughing-up of stubble.

The working tools each consist of a claw and a spring, fixed together on the rotating axle, without screws or bolts ; they are interchangeable and easily replaced if broken. The wear of the claws depends on the kind of soil ; in rocky soils or for certain work it is advisable to use the machine as a plough-tractor.

The " Motoculteur " is provided with special seeders, and it ploughs, harrows down, sows and rolls all in one turn (cereals, maize, beets, etc.). It can be used for planting potatoes, the fertiliser being sown simultaneously. When standing at the farm, its engine drives the fixed farm machinery. A single workman is always sufficient to drive the " Motoculteur ", no matter what the work is.

According to M. FRÉMIER, the work done by the " Motoculteur " seems to be all that could be desired from the point of view of modern agricultural science. In a single turn, it will obtain that uniform structure in the whole layer of earth worked that is necessary for a perfect *seed bed*. According to the crop, and according to the soil, be it dry, wet, or even pebbly, the size of the clods and the fineness of tilth required are easily regulated. When the soil is covered with a normal layer of farmyard manure, the machine mixes it intimately with the soil throughout the cultivated layer, thus favouring nitrification. Only a small part of the longer straws and residue remains visible on the surface. As for other fertilisers and dressings, the motoculteur mixes them evenly throughout the cultivated layer. If the machine is used on land covered with vegetation (lucerne, mustard, vetches, lupins, etc.) or stubble, it tears the plants to pieces and buries the fragments. However, for such work which is heavy on the engine, sharper claws placed closer together should be used.

85 - Howard's "Imperial" Disc Harrow. — *The Implement and Machinery Review*, Vol. 43, No. 517, p. 722, 1 fig. London, November 1, 1917.

The "Imperial" steel disc harrow, illustrated below, is constructed by Messrs. J. & F. HOWARD, of Bedford, England. The transport wheels at the rear of the implement can be easily raised during working, and, conversely, the harrow raised for travelling. By a lever, the discs can be adjusted to suit the peculiarities of the ground. The fore-carriage possesses a rocking movement from which great advantage is derived on rough and rocky land. This disc harrow is suitable for attaching behind a plough towed by a tractor. It is made in four widths, with 12, 14, 16 and 20 discs of either 18 in. or 20 in. diameter.

HOWARD'S Imperial Disc Harrow.

86 - Mower for Gathering Kelp, in the United States. — See No. 19 of this *Review*.

87 - The Baldwin Standing Grain Thresher. — *Farm Implement News*, Vol. XXXVIII, No. 79, p. 25, 1 fig. Chicago, September 27, 1917.

This machine, reproduced below, does not head the grain, but draws the heads into a threshing cylinder which shakes out the kernels and leaves

The BALDWIN Standing Grain Thresher

the straw standing uncut. It handles a 12-foot swathe. The machine is drawn by horses or a tractor, but the operating mechanism is driven by a WANKESHA motor. All the gears are enclosed and HYATT roller bearings are used extensively.

The grain is delivered into sacks by the machine. One or two men suffice for attention. In regions where there is little fear of lodging and where all the grain ripens at the same time, the machine should save a deal of hand-labour.

A number of the machines are already in use in western Nebraska, Kansas and Texas.

88 - **The Rebuffel "Olive Gleaner"**. — REBUFFEL, A., in *Republique Française, Office National de la Propriété Industrielle, Brevet d'Invention No. 484560, 1 p. + 6 figs* Published at Paris on October 18, 1917.

A new apparatus, called the "Olive Gleaner", for rapidly collecting fallen olives.

The appended figure shows the longitudinal section of the apparatus, as well as the upper surface of the handle. The device consists of a small board *D* bearing a number of points *F*, through which a lattice ejector *E*

REBUFFEL'S "Olive Gleaner"

works on pressing the lever *C* to the handle *B*. By means of the spring *R*, the ejector-lever takes up its former position on releasing the pressure. The spring *R*, whose pivot *G* is fixed to the handle *B*, is attached to the lever by a screw *Q*; the action of the spring is helped by the mortise *M*. The heads of the points *F* of the piece *D* are held in position by a plate *S*, placed under the upper board *D*; these two boards are fixed to the handle *B* by both back and front sides *K* and *U* respectively, leaving a hollow, *T*, between them. The ejector *E* is fixed on the lever by a screw *P* passing through its end and held by a wedge piece.

To use the apparatus, it is taken in the hand, the points turned towards the soil. The olives are collected by striking them from above downwards, when they are pierced by the points. When the points are full of olives, the apparatus is held over a basket, and on pressing the lever, the ejector moves up and removes the olives, which fall into the basket. If there are great numbers of fallen olives, the workman may use a second apparatus for the left hand.

89 — The "Alpha" Apparatus for the Discovery of Metallic Objects in the Soil. — *Le Génie Civil*, Vol. I,XXI; No 19, pp. 312-313, fig. 2. Paris, November 10, 1917.

From the data of M. GUTTON, who devised a machine for tracing projectiles buried in the soil, M. CHANOIT, Engineer, of Villeneuve-Saint-Georges, has constructed a new "Alpha" apparatus (so called because of its A-shape), by means of which a 75 shell buried 16 to 20 ins. in the soil may be located.

By means of the apparatus, any metallic object weighing 22 lbs and buried up to 20 ins. deep in the soil may be located.

The apparatus, based on the principle of the HUGHES induction balance, consists of 4 exploring coils wound two by two round two horizontal plates or circles of wood of 24 in. diameter and suspended at the ends of two wooden arms inclined at 45° towards the soil, and held firm by a cross member. The parts are all jointed. The centres of the plates are about 59 ins. apart, so that the apparatus controls a distance of about 82 ins. The regulating device is placed on the angle formed by the two inclined arms; it includes two enclosed coils, connected to the two rolls of wire fixed on the plates. Ordinary telephone receivers, carried by a telephonist's cap, are used as detectors.

A pile of 2 or 3 elements and a Ruhmkorff coil with a trembler provide the current. Both induction coil and pile are contained in a portable box, and joined to the exploring apparatus by long wires. Such as it is at present, the apparatus indicates the presence of a metallic mass buried about 20 ins. in the soil by means of the resonance of the telephone. As yet, such objects can only be discovered at a slight depth, but experiments are being carried out to increase its efficiency.

The instrument is light and easily handled, being entirely constructed in wood. It can be partly unmounted and folded to assist its transport.

## RURAL ECONOMICS.

RURAL  
ECONOMICS

91 — **The Milk Producer's Problem in the United States.** — GILLETTE, I. S. (Iowa State College), in *Hoard's Dairymen*, Vol. LIV, No. 11, pp. 324. Fort Atkinson, Wis., October 5, 1917.

There is no industry which is suffering as severely in the present crisis as that of milk production, while one-fifth of the total food supply of the United States is the dairyman's task.

The accompanying table shows the average price which the dairy farm operated by the Iowa State College was compelled to pay for feeds during the years July 1, 1914, to June 30, 1915, and July 1, 1916, to June 30, 1917, as well as the market quotations of the same feeds August 1, 1917. It shows that in the two year interval the price of feeding stuffs has increased from 70 to 205 %, as in the case of corn. Alfalfa hay is not quoted, but it will reach the highest price this winter to which it has ever soared. The problem of the dairyman, therefore, seems to be the utilization of feeding stuffs that have increased 100 to 200 % in cost for production of dairy products that are selling for only 25 % more than formerly.

Dairy farming has never been noted for large returns; its popularity is based upon the certainty of the income, usually at a small profit. Now, the great increases in the cost of production brought about largely by the rise in cost of labour, increased value of cows and price of feeding stuffs transform the profit to a loss. The relief must be sought principally in :

- 1) Higher prices for product.
- 2) Elimination of the boarder cow.
- 3) Economical selection of concentrates

Of these factors the first one is of primary importance and will be achieved through education of the consumer and organization of the producer. The second factor determines the degree of profit of the dairyman regardless of the price received for the product. A too large percentage of boarder cows will make any dairy a financial liability. The last factor is one which varies rather widely with the locality, season and year. While roughages are much more expensive than formerly they are still the cheapest source of food nutrients. In those herds which are kept for commercial milk production the more limited use of concentrates is the practical policy to pursue. Silage is a cheaper source of energy for all kinds of dairy stock than alfalfa and no dairymen with even a small herd can afford to be without it because of its succulence, palatability and economy.

*Prices of feeding stuffs per cwt.*

Feed	July 1, 1914 June 30, 1914	July 1, 1916 June 30, 1917	August 1, 1917	% increase

## AGRICULTURAL INDUSTRIES.

93 - Methods for Determining the Adulteration of Wines. — PRATOLONGO, UGO, in *Le Stazioni Sperimentali Agrarie Italiane*, Vol. I., Pt. 6-7-8, pp. 315-361. Modena, 1917.

The chief methods for determining the adulteration of wine are examined separately.

The essential condition which any such method must fulfill is that it must be possible to distinguish clearly between natural and adulterated wines so that the dividing line includes *all* the natural wines and *these* wines only. Up to the present no method has been found fulfilling this double condition; each of them, while answering to one of the conditions, sacrifices the other more or less.

In order to determine the true value of the various methods the author examined 560 natural Italian wines, using analytical data supplied by the publications of the Italian Ministry of Agriculture.

The author gives a table on which are 2 curves interpreting the various methods examined, the alcohol content of the wines being represented by the abscissae and their acidity expressed as grammes of tartaric acid per litre, by the ordinates.

GAUTHIER'S *method*. — The total alcohol + sulphuric acidity must exceed a minimum value, fixed by Gauthier at 13, and reduced by the French Committee of Arts and Manufactures, to 12.5, and fixed at 12.5 and 11.5 for table wine and Aramon wine respectively by the French official methods. Expressing the alcohol content of the wine by  $g$ , its acidity, expressed as grammes of sulphuric acid per litre, by  $a_s$ , and the constant whose value is equal to 12.5 by  $C$ , the following formula is obtained:  $g + a_s > C$ .

This method includes *all* natural wines (of 560 natural wines only one appeared adulterated), but does not include *only* these wines (20 % of method).

INDUSTRIES  
DEPENDENT  
ON PLANTS  
PRODUCTS

HALPHEN'S *method*. — This is expressed by the formula

$$a_s > 1.160 - 0.07 g$$

(the letters having the same signification as above).

Placing this formula in the form  $a_s > 1.160 g - 0.07 g$ , the maximum acidity would be obtained with  $g = 8.28$ . As this has in no way been proved the author considers the rule to have no rational basis.

Contrary to that of GAUTHIER this rule fulfills the just condition (the inclusion of *all* the natural wines) very imperfectly, but better satisfies the second (the inclusion of these wines *only*). In the experiments made,  $\frac{1}{5}$ th. to  $\frac{1}{6}$ th. of the natural wines wrongly appeared adulterated.

The author tried whether the modification introduced by POSSETTO and ISSOGLIO, and later by GALEAZZI (i. e. the introduction into the calculation of the ratio acidity : alcohol of the limit 0.120) really improved the results obtained. The diagram appended to the paper shows that HALPHEN'S rule thus modified answers the first condition, but no longer answers the second satisfactorily.

BLAREZ' *method*. — BLAREZ has given in table form the minimum acidity corresponding to each degree of alcohol by dividing natural wines into 5 categories and giving to each a dividing line between natural vines and adulterated wines.

The author's diagram shows BLAREZ' method to answer the double condition much better than the others, because it excluded the smallest quantity of natural wines and reduces to a minimum the possibility of not discovering adulteration.

ROOS' *method*. — This may be expressed as follows: — the total *alcohol + acidity* is in inverse proportion to the ratio *extract : alcohol*. According to ROOS, this coefficient is always below 25.6 in natural wines, but never below 24 in adulterated wines.

This rule has about the same value as that of GAUTHIER.

CONCLUSIONS. — BLAREZ' method is the most satisfactory, although applied without modification to Italian wines it would allow too much adulteration. It must be placed within closer limits.

Taking his diagram as a basis, the author divides natural wines into 2 categories according to their composition. The first includes the greater number of natural wines, which the author arbitrarily calls "wines of normal composition". The second includes nearly all the natural wines not contained in the first (58 out of 560 in the author's experiments, i. e., about  $\frac{1}{10}$ ) and called "wines of abnormal composition". The figures fixing the limits of the 2 categories of natural wines are given in 2 tables.

In order to apply these methods, all Italian wines of non-declared origin may be placed in the 1st. category. The wines of the second category could only be used commercially with a declaration of origin which would justify their abnormal composition. Wines of a composition below the limits fixed by the second category should be considered adulterated unless proof to the contrary can be furnished.

1st. category Wines of normal composition		2nd. category Wines of abnormal composition

94 — The Use of Horse-Chestnuts for the Production of Alcohol (1). — KAYSER, in *Feuille d'Informations du Ministère de l'Agriculture*, Year 22, No. 45, p. 10. Paris, November 6, 1917.

The author (Director of the Fermentation Laboratory of the National Agricultural Institute) gives the following figures for the content of the horse-chestnut in carbohydrates and nitrogen, comparing them with those of maize and rye.

Description	Composition per cent		
	Moisture	Nitrogen	Carbohydrates
Fresh undecorticated horse-chestnuts . . . .	49.2	4.8	40.9
Dried " " " " . . . .	18.8	6.9	53.7
Fresh decorticated " " " " . . . .	51.0	3.9	39.2
Dry " " " " . . . .	10.5	7.2	71.8
Average maize . . . . .	13.0	9.9	69.2
Average rye . . . . .	13.4	11.5	69.5

The horse-chestnut has an average content of 0.5 % of potassium and 0.15 % of phosphoric acid, foods necessary to alcoholic fermentation.

Experiments carried out by the author show that the yield of 27 to 28

(1) On the use of horse-chestnuts, see: — R. October, 1917, No. 954; R. December, 1917, No. 1185. (Ed.)

litres of alcohol per 100 kg. of dry horse-chestnuts, although inferior to that of maize, is sufficiently high, in view of the moderate cost of the chestnuts (12s. 8d. per 100 kg. of dry nuts), to justify their use for making alcohol in war time.

- 95 — **Utilisation of Acorns by Acoholic Fermentation.** (1). — KAYSER, in *Feuille d'Informations du Ministère de l'Agriculture*, Year 22, No. 19, pp. 9-10. Paris, December 4, 1917.

The author (Director of the Fermentation Laboratory) describes the results obtained by the alcoholic fermentation of sweet acorn juice.

The experiments were carried out with three varieties of oak, pedunculate, sessile and holm, found in the Mediterranean district. Whole acorns and kernels were used. The sweet liquid was obtained by treating the acorns (without the cups), cut into small pieces with twice, and sometimes four times, their weight of water in the presence of 2.5 % of hydrochloric acid or 1 % of sulphuric acid during half an hour in the autoclave at 120-122°C. The sweet liquid is filtered off, the solid residue being crushed in a mortar and treated with hot water till the liquid is completely extracted. The liquids are neutralised with potash up to an acidity of 1 % in sulphuric acid.

Either grain or cider yeast was added to the sterilised liquids. Fermentation usually started after 24 hours, rather more rapidly in flasks to which had been added from 1 to 2 % of sweet rye extract (nitrogenous and phosphatic food), more rapidly also in those of greater dilution, which is comprehensible, for an excess of tannin, of which acorns contain a fairly large proportion, prevents alcoholic fermentation.

Grain yeast gives a yield slightly higher than that obtained with cider yeast.

The yield from whole acorns varies from 8.58 to 20.16 litres of alcohol per 100 kg. of dry material, whereas for the kernels, it may amount to as much as 28, 29 or 31 litres. This yield is higher than that obtained by the author for horse-chestnuts, although, in a certain sense, these fermented more easily (2). The yield varies with the degree of ripeness, the variety, and, above all, the dilution (influence of the tannin).

It is best to use dry acorns, freed from their cups by threshing and sifting.

- 96 — **Unsalted Lime Bread.** — See No. 3 of this *Review*.

- 97 — **The Problem of Sugar Manufacturing in India.** — WYNNE, SAYER, in *The Agricultural Journal of India*, Vol. XII, Part. IV, pp. 550-565. Calcutta, October, 1917.

After a thorough examination of the problem of the Indian Sugar Industry in its different aspects, the writer, summing up his various points of view, makes the following statement: The problem of the Indian Sugar Industry is a two-fold one, and energetic measures should now be set

(1) On the use of acorns as a food for cattle see No. 66 of this *Review*. — (2) See No. 94 of this *Review*. (Ed.)

on foot to place both the *gur* and the white sugar industries on a satisfactory working basis. To do this properly will require a survey to be made of the localities where white sugar factories can be erected, and at the same time the districts where the cane cultivation is only capable of carrying a *gur* factory should be carefully recorded. The financial side of the matter and the question of State assistance to the pioneer factories also require to be carefully examined.

To do this will require a strong committee of experts who will also be able to report to Government how far the manufacture of sugar on a considerable scale together with its by-product — alcohol — can be made the subject of excise control in India. The question of the creation of a special sugar department for India for tackling and coordinating the numerous manufacturing, agricultural, botanical and chemical problems connected with the industry could also be dealt with, but the main question is to get it dealt with at once, for, at present, Indian sugar is being made under most favourable conditions and this state of things, which gives an insight into the possibilities of the industry in India, when foreign competition is lacking or curtailed, will not last for long, and if the industry, which is now in places getting its head above water, is allowed to be stifled again by unfair competition, it will not readily respond to efforts made in the future to resuscitate it.

98 — **The Manufacture of Sugar in the Republic of Salvador.** — See No. 46 of this *Review*.

99 — **The Utilisation of Grape Residue as Fuel.** — MATIGNON, C. and MARCHAL, G., in *Comptes Rendus des Séances de l'Académie des Sciences*, Vol. 165, No. 21, pp. 718-721. Paris, November 19, 1917.

A thermal study of grape residue showed it to have about the same value as peat as a fuel. Its thermal constants, chemical composition and ash content, are exactly similar to those of peat. There is no doubt that it might be used, like peat, in suitable stoves. Experiments on this subject will shortly be carried out with the residues from the last harvest.

In a normal average year, with a French production of 50 million hectolitres of wine, it would be possible to obtain, after distillation, residues having a calorific value equivalent to more than 160 000 metric tons of coal.

100 — **Celery Storage Experiments.** — THOMPSON, H. C., in *United States Department of Agriculture, Bull. No. 579*, pp. 26, 10 figs., 17 tables. Washington, September 5, 1927.

Celery growing is of great importance in the United States. The farm value of the crop in 1909 was \$ 3 922 848, but, as a considerable portion of this is stored for one to three months, its commercial value is much superior to the farm value given.

This value may be increased by good storage methods. The old methods are gradually being given up more and more in favour of cold-storage. In spite of this, celery is so difficult to store that many warehouses prefer to devote themselves to other products.

Very few data on the cold storage of celery are available. The expe-

AGRICULTURAL  
PRODUCTS;  
PRESERVING,  
ETC.,

periments carried out by the United States Department of Agriculture during period of four years, 1912-1910, aimed at determining :

- 1) The factors which hasten decay in celery in storage houses.
- 2) The best methods of reducing the loss of celery in storage due to decay and mechanical injury.
- 3) The best type of crate in which to pack celery to be cold-stored.
- 4) The effect of the temperature of the storage room on the keeping quality of celery.

The experiments were carried out in three cold-storage warehouses, Elmira, Hornel and Williamson, N. Y.

Large crates are favourable to decay, which begins in the centre. Injury to the celery is chiefly due to the breaking of the crates.

The celery suffered less injury when packed in smaller crates and in those with a longitudinal or transversal ventilation partition down the centre. The 14 inch crate gave the best results, followed by the 16 inch crate and the 11 inch crate. The standard crate varies in size from 22 to 24 by 24 inches. Small crates, though slightly more expensive than large ones, are preferred by many cold-storage warehouses because it is easier to handle them and the proportion of broken crates is smaller.

A market test showed that celery stored in small crates sells for a much higher price than that in standard crates handled in exactly the same way.

The crates were piled up in five tiers. The celery in the top tier was decayed in a larger proportion than that in the lower tiers.

There was a greater difference in the keeping quality of the celery in the different tiers in standard crates than in the other crates.

The difference in the keeping quality of the celery in the different tiers is probably due to the difference in temperature of the room at different heights. The temperature of the air at the fifth tier averaged 2.4° F. more than that of the first tier. The temperature of the celery in standard crates averaged 2.7° F. higher at the fifth tier. The temperature of the celery in the standard crate averaged 2° F. higher than in the partition crate and 4.1° higher than the air at the same height.

In order to check properly the temperature of the room, thermometers should be placed at different heights. In many cases when the temperature at 4 feet from the floor was 32° F., that near the ceiling was found to be from 35 to 39°.

101 - The Cost of Cattle Foods in the United States, from 1914 to 1917. — See No. 91 of this *Review*.

## PLANT DISEASES

### DISEASES DUE TO FUNGI, BACTERIA AND OTHER LOWER PLANTS.

102 - New Japanese Fungi (1). — TANAKA, TYOZABURO, in *Mycologia*, Vol. IX, No. 6, pp. 364-368. Lancaster, Pa., November, 1917.

GENERAL

This third note gives an English translation of the systematic descriptions, originally published by the authors in Japanese, of the following new species of fungi.

1) *Massaria moricola* I. Miyake n. sp. (published in December, 1916), common on twigs of *Morus alba* in the following localities: — Gifu-ken (prefecture), Kaidzu-gun Kaisaimura (1909); Fukui-ken (pref.); Ōno-gun and Hida-no-kuni (Gifu prefecture), Mashita-gun, Shimohara-mura (1909); Nagano-ken (pref.), Shino-ina-gun (1910); Tokyo-fu (pref.), Nakano-chō (1915); Tochigi-ken (pref.), Utsunomiya-shi and Fukushima-ken (pref.), Fukushima-shi (1915); Kyoto-fu (pref.); Ayabe-chō (1915).

2) *M. japonica* I. Miyake n. sp. (December, 1916); not common, on twigs of *Morus alba* in the following localities: — Gifu-ken (pref.), Ena-gun Kashimo-mura (1909); Iwate-ken (pref.); Hanamaki-chō (1915).

3) *Mycosphaerella Hori* K. Hara n. sp. (March, 1917) on leaves of *Citrus*; type localities: — Hamana-mura, Inasa-gun, Shidzuoka-ken (1914), Katarō, Shimidzu; Japanese name of disease: Kashaku "Ko-maruboshiyō"; Dr. SHÔTARÔ HORI considers the cause of this disease to be *Phyllosticta curvatispora* Hori n. sp.,; as no description of the fungus is given it is impossible to determine whether it is a form of *Myc. Hori*, but the existence of such a relationship is very probable; according to HORI the fungus mostly attacks the navel variety of *C. sinensis* and *C. nobilis* var. *unshiu* (Unshu [Satsuma] orange);

4) *Phyllosticta citricola* Hori, n. sp. (published in July, 1913, without description, and published again in March, 1917); on leaves of *Citrus*; type localities: — Toyoda-mura, Abe-gun, Shizuoka-ken (1914); Japanese name of disease: — "Kasshoku Ō-maruboshiyō"; the same disease is reported to have caused great injury to the Japanese summer orange ("Natsudaidai") in the province of Toyoda-gun (Hiroshima-ken), and also in Abe-gun, Shidzuoka-ken; HORI reported it as also attacking *C. nobilis* var. *unshiu*.

(1) See also R, Oct., 1917, No. 965. (Ed.)

103 — **New or Noteworthy North American Fungi.** — DEARNESS, J., in *Mycologia*, Vol. IX, No. 6, pp. 345-364. Lancaster, Pa., November, 1917.

The list includes 51 species of fungi either new or worthy of note, collected at different times in various districts of North America. A systematic description is given of the numerous species new to science.

Special mention should be made of the following: —

- 1) *Asterina (Asterella) fumagina* Dearn. and Barth., n. sp., on living leaves of *Panicum latifolium*, Maricao, Porto Rico;
- 2) *Phacidium Gaultheriae* Dearn., n. sp., on living stems of *Gaultheria Shallon*, Vancouver Island;
- 3) *Exoascus Aceris* Dearn. and Barth. n. sp., on living leaves of *Acer grandidentatum*, Parley's Canyon, Utah;
- 4) *Cicinnobolus major* Dearn. and Barth., n. sp., on *Oidium* on living leaves of *Grindelia squarrosa*, Billings, Mont.;
- 5) *Septoria samarae-macrophylli* Dearn. and Barth., n. sp., on green samarae of *Acer macrophyllum*, Duckabush River, Wash.;
- 6) *Sept. Sarcobati* Dearn. and Barth., n. sp., on the calyx of *Sarcobatus vermiculatus*, Tromberg, Month.;
- 7) *Melasma Menziesiae* Dearn. and Barth., n. sp., on living leaves of *Menziesia ferruginea*, Duckabush, Wash.;
- 8) *Gloeosporium Ailanthi* Dearn. and Barth., n. sp., on living leaves of *Ailanthus glandulosa*, Shreveport, La.;
- 9) *Gl. Bartholomaei* Dearn., n. sp., on living leaves of *Ribes bracteosum*, Port Orchard, Wash.;
- 10) *Gl. Betae* Dearn. and Barth., n. sp., very injurious to sugar-beet leaves, Billings, Mont.;
- 11) *Gl. Crataegi* Dearn. and Barth., n. sp., on living leaves of *Crataegus brevispina*, Vancouver, Wash.;
- 12) *Marssonina bracteosa* Dearn. and Barth., n. sp., on living leaves of *Ribes bracteosum* attacked by *Gl. Bartholomaei*, Port Orchard, Wash.;
- 13) *Septogloeum Nuttallii* Hark., on living leaves of *Osmaronia cerasiformis*, Vancouver Island;
- 14) *Sept. Schizonoti* Dearn., n. sp., on living leaves of *Schizonotus discolor*, Vancouver Island;
- 15) *Sept. Salicis-Fendlerianae* Dearn. and Barth., n. sp., on living leaves of *Salix Fendleriana*, Caldwell, Idaho;
- 16) *Cylindrosporium Artemisiae* Dearn. and Barth., n. sp., on living leaves of *Artemisia Suksdorfii*, Pleasant Beach, Wash.;
- 17) *Fusoma rubricosa* Dearn. and Barth., n. sp., on living leaves of *Calamagrostis scabra*, Glacier National Park, Mont.;
- 18) *Ramularia Clematidis* Dearn. and Barth., n. sp., on living leaves of *Clematis ligusticifolia*, Billings, Mont.;
- 19) ? *Cercospora Aceris* Dearn. and Barth., n. sp., injurious to living leaves of *Acer macrophyllum*, Duckabush, Wash.;
- 20) ? *C. Alni* Dearn. and Barth., n. sp., injurious to leaves of *Alnus rubra*, Bremerton, Wash.;
- 21) *Cercospora Streptopi* Dearn. and Barth., n. sp., on living leaves of *Streptopus amplexifolius*, Duckabush River, Wash.

104 - **Rust Resistant Manitoba Wheat, in France.** — See No. 34 of this *Review*.

105 - **Vines Offering a Relative Resistance to Mildew.** — SALOMON, RENÉ, in *Revue de Viticulture*, Year 24, Vol. XLVII, No. 1220, pp 314-316. Paris, November 15, 1917.

A list of French vines is given which, in any kind of year, give a full harvest, and which, even in 1917, were perfectly immune to mildew of the fruit with four sprayings only.

I. **WHITE GRAPES.** — “Meslier Saint-François” or “Meslier du Gâtinais”; “Meslier hâtif”, too well known to require description.

“Meslier rose”, less productive than “Saint-François”, yielding as much as 1 780 gallons per acre of a colourless wine which keeps excellently, but more productive than “Meslier hâtif” with an equivalent choice table wine.

These three varieties are easily protected however violent the attack may be. They are closely followed by :

“Aubin blanc” (Lorraine), late 1st. period. Strong and of regular yield (short pruning). At Euvezin (Meurthe-et-Moselle) this plant has given extraordinary harvests.

“Bouquetriesling”, “Feinriesling”, “Firnriesling”, “Goldriesling” 1st period. Obtained from OBERLIN (Alsace). Strong and fertile. First cultivated in Auvergne experimentally, are now gradually grown over an increasingly large area, especially “Goldriesling” (medium pruning)

Next come the following, which are also easily protected :

“Ezer Jo”, early 2nd. period, very fertile. Enormous yield. Very fine appearance (short pruning).

“Fernand rose” (OBERLIN), early 1st. period. Very heavy yield (short pruning). Mixed vat and table wines.

“Gros Pinot blanc hâtif”, 1st. period, vigorous and fertile. Selection of “Pinot blanc Chardonnay”. The most resistant of all “Pinots blancs” to oidium (long pruning).

“Putzcheere”, early 2nd. period, called, on account of its extraordinary fertility “Aramon du Nord”, strong plant (short pruning).

“Sylvaner blanc”, late 1st period. Heavy yield of a light, sweet, pleasant wine (short pruning).

“Tantovina”, 2nd. period. Very heavy yield. Wine identical with that of “Meslier du Gâtinais” (short pruning).

“Traminer rose”, late 1st. period, in great demand in Alsace, where it produces excellent wine (long pruning).

“Weisser Klœvner” or “Pinot blanc vrai”, 1st period, Alsace, excellent quality wine (long pruning).

II. **RED GRAPES.** — “Lasca”, 1st. period, adapts itself to almost all exposures; very good wine; very resistant to rot (ample pruning).

“Magyar Traube”, early 1st. period, heavy yield, mixed vat and table (cordon pruning).

“Patte d’oie”, 1st. period, good plant, regularly fertile (short pruning).

These are closely followed by :

“Gamay teinturier supérieur”, 1st. period; yield equivalent to that of “Fréau”, but wine less acid, and flowing differently (medium pruning).

"Gougenot", late 1st. period, shoots open fairly late, gives a light, very refreshing wine (medium pruning).

"Limberger", late 1st. period gives an abundance of good table wine (long pruning).

"Melascone nera", late 2nd. period, "Pinot" to be recommended for its fertility and the superior quality of its wine (long pruning).

"Pinot noir Saint-Laurent", late 1st. period, "Pinot" giving a yield double that of the best selected "Pinots"; excellent quality wine, resistant to black rot (long pruning).

"Pinot Renevey amélioré", 1st. period, selection of "Pinot noir", but with a heavier yield (long pruning).

CROPS

106 — **Patents for the Control of Diseases and Pests of Plants.** — See No. 95 of this *Review*.

107 — **Observations on Hemp Mildew (*Peronoplasmopara cannabina*) in Italy.** — PEGLION, VITTORIO, in *Rendiconti delle sedute della Reale Accademia dei Lincei*, Classe di Scienze fisiche, matematiche e naturali, Vol. XXVI, Pt. II, pp. 618-620. Rome, 1917.

Repeated observations on the presence and behaviour of "hemp mildew" carried out for about ten years in the province of Ferrara, confirm the fact that, except in rare cases, this parasite is practically of no importance. Nevertheless the great frequency with which it is found in the very conspicuous form of conidial fructifications, lead the author to study it anew.

He found the first spots on plants which had already put forth their third and fourth stages of leaves. These spots were fairly large and not accompanied by deformation of the leaves of the first node, and were often confined to a longitudinal portion of the leaflet, which curves over in the form of a scythe when the leaves of successive nodes are infected. If the young plants showing signs of mildew on the first leaves are carefully pulled up and put in very damp and dark surroundings, large efflorescences of conidiophores form in 24 hours, even on the upper stages of the leaves. Only after some hours does the part occupied by the conidiophores show signs of chlorosis and turn brown.

If, on the other hand, the plants are left under their normal conditions of growth, these abundant fructifications of the parasite only occur on the leaves already infected. If the plants are left 3-4 days under these environmental conditions, a microscopic examination shows the presence of oospores in the brown, mildewed tissues, which form a source of decay. Oospores form very rapidly on loose mildewed leaves kept in a damp room but in limited numbers.

Oospores form regularly in the seed leaves, even under normal environmental conditions. On all the plants showing mildew spots on the cauline leaves, a microscopic examination of the remains of the cotyledons showed the presence of oospores and of a thick efflorescence of conidio-

phores. This implies that infection of the young plant takes place dur-

ing germination. Infection experiments were carried out with conidia on pot cultures of hemp immediately after germination. Three or four days later the cotyledons of a fairly large number of the young plants were covered, on both sides, with a thick brown efflorescence formed of conidiospores of the parasite.

The presence of a papilla at the extremity of the conidia made it appear probable that the fungus in question had been wrongly placed in the genus *Peronospora*; and, indeed, close observation of the germination of the conidia showed them to behave like true zoosporangia. In order to follow their development young hemp plants germinating under glass were used. Conidia were sown in the drops of water which had condensed on the cotyledons, and, at the same time, conidia were sown in drops of distilled water in the usual damp rooms. In both cases, after a period of time varying from one to two hours, the protoplasmatic contents begin to divide, the papilla at the end disappears, and well-defined zoospores, which move rapidly within the conidial wall, slip through the narrow opening made at the end of the conidia; each conidium usually produces three very motile zoospores with two flagella. One or two hours after they have emerged, they become immotile, lose their flagella, become spheroid with differentiation of a thin wall, then develop a single or branched germination tube, which moves along the epidermis to the nearest stomate.

The dichotomous ramification of the conidiospores and the germination of the papillate conidia by zoospores shows the parasite of hemp to resemble "melon mildew", which has been moved from the genus *Plasmopara* (*Pl. cubensis*) by BERLESE, who proposes to class it, with *Pl. celididis*, in the sub-genus *Peronoplasmopara*. ROSTOWZEW, without taking BERLESE's observations into account, created the genus *Pseudoperonospora* in order to bring out the characteristics of this fungus, but, as has been observed by CLINTON, the sub-genus *Peronoplasmopara* deserves precedence both on account of priority of publication and its well-defined characters. The parasite of hemp therefore no longer belongs to the genus *Peronospora* and must be placed in the genus *Peronoplasmopara* (*Peronoplasmopara cannabina* [Oth.] Pegl.).

108 - The "Irish Gold" and "Broad Leaf Burley" Varieties of Tobacco Attacked by *Thielavia basicola*, in Ireland. — See No. 49 of this Review.

109 - Black Rot Disease of Tea. — PERCH, T., in *Department of Agriculture, Ceylon, Leaflet* No. 2, pp. 3, 2 figs., Colombo, Ceylon, February, 1917.

In two districts in the low country a new disease of tea has recently appeared. This disease, commonly called black rot disease, appears chiefly on the leaves, but it may attack all the aerial parts of the plant.

Attention is usually drawn to the affected bushes by the blackening of the young leaves; the more tender ones at the tops of the shoots turn black, soft and rotten. The chief characteristics of the disease are the persistence of hanging dead leaves and the occurrence of dead leaves united in clusters of two or three, or joined to the stem by a mycelium.

The fungus causing the disease — *Hypochnus* sp. of the Thelephoraceae

family — consists of very fine threads, usually invisible to the naked eye, which spread along the stems and under surface of the leaves, to which they are generally confined, giving off branches which penetrate into the living tissues of the plant and kill them. It does not appear to cause any damage on the old stems, but on the young ones it causes premature hardening in the form of scaly grey-brown patches.

On the young leaves the fungus produces small blackish-brown or chocolate-brown spots, which run into one another and form a patch which gradually extends over the whole surface. The action of the fungus is not so general on the old leaves, only part being attacked as a rule.

The disease passes from the stalk to the leaf by means of the leaf stem, but healthy leaves may be infected by contact with diseased ones.

The disease usually occurs in patches scattered over the field. There is reason to believe that the fungus is an inhabitant of the Ceylon jungle and spreads from the jungle to the tea. On one infected estate it was found on an isolated group of jungle shrubs, on Gurukina (*Calophyllum Burmanni*) and Iramusu (*Hemidesmus indicus*).

Infection experiments on tea at Peradeniya have, so far, failed completely. This does not mean that the fungus will not attack tea at Peradeniya or greater heights.

The *Hypochnus* may be found to be still alive on prunings left in the field at least two months after pruning.

As the fungus lives on the stems and branches, diseased plants must be pruned well back, and, since it continues to live on the prunings, these must be removed and burnt. As, also, the parasite may still exist on the older stems, the pruned bushes must be well sprayed with Bordeaux mixture.

110 — A Disease of the Hemlock Tree. — MURRILL, W. A., in *Journal of the New York Botanical Garden*, Vol. XVIII, No. 213, p. 208, Lancaster, Pa., September, 1917.

A disease of the hemlock tree (*Tsuga canadensis*) caused by *Fomitiporia tsugina* Murrill was discovered by Mr. PERCY WILSON at East Hebron, New-Hampshire, in August, 1905.

In July, 1917, Mr. WILSON again visited the district and collected specimens of the fungus from the trunk of the same tree, which he found dead and lying on the ground.

Living hemlocks near Bristol, New Hampshire, examined by Mr. WILSON, were also found to be attacked by the fungus, which exists in New York as well as in New Hampshire, attacking only the hemlock tree.

The disease is probably important and should be studied by foresters as well as by mycologists.

## INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

- 114 - Scolytid Beetles Observed in Oregon (United States). — CHAMBERLIN, W. J., in *The Canadian Entomologist*, Vol. XLIX, No. 9, pp. 321-328; No. 10, pp. 353-356. London, 1917.

GENERAL

The following beetles have been observed in Oregon at different times :

- 1) *Conophthorus ponderosae*, Hopk., collected at Corvallis;
- 2) *Conophthorus* sp. : 3 adults bred from cones of *Pinus contorta* collected at Corvallis;
- 3) *Cryphalus amabilis* n. sp., made small chambers in many branches of *Abies amabilis* near Elk Lake; the trees looked sickly and the foliage of many branches was turning red;
- 4) *C. subconcentralis*, Hopk., collected at Astoria;
- 5) *C. grandis* n. sp., abundant on *A. amabilis* near Corvallis;
- 6) *Crypturgus* sp., working in the dead bark near the top of a dead fir (*Abies lasiocarpa*) near Sumpter;
- 7) *Dendroctonus valens*, Lec., rather common throughout the pine regions of Oregon; especially abundant in *P. ponderosa* in Eastern and Central Oregon; occasionally found at the base of the larger specimens of *P. contorta*; noted at Corvallis, Hood River, Bend, Crescent, Sumpter, Sparta, Ashland and on the Kilamath Indian Reservation;
- 8) *D. monticolæ*, Hopk., found throughout the State on *P. ponderosa*, *P. contorta*, *P. monticola* and *P. Lambertiana*; it has caused heavy losses in North-Eastern, Central and Southern Oregon;
- 9) *D. engelmanni*, Hopk., this species has not before been recorded from this State; the writer collected 2 dead adults from their characteristic mines under the bark of *Picea engelmanni* near Sumpter in the Blue Mountain Region of North-Eastern Oregon;
- 10) *D. brevicornis*, Lec., this is the most serious pest of pine in Oregon and causes the death of a very large amount of the largest and finest pine (*P. ponderosa*) timber of Eastern, Central and Southern Oregon; thousands of dollars are expended annually in combating the pest;
- 11) *D. pseudotsugae*, Hopk., found in all parts of the State where *Pseudotsuga taxifolia* grows; the beetles seem to prefer injured or fallen timber, but will attack living healthy trees, as is shown by a serious infestation in South Washington and near White Pine, Oregon, where several thousand trees were killed;
- 12) *D. obsesus*, Mannh., a rather rare beetle working in the cambium of *Picea sitchensis*; at Marshfield and Astoria;
- 13) *D. jeffreyi*, Hopk., this species is reported by HOPKINS as occurring in South-West Oregon; the writer, however, has seen no species working in this State
- 14) *Dolurgus pumilus*, Mannh., on *Picea sitchensis*;
- 15) *Dryocoetes autographus*, Ratz., a number of specimens referred to this species were collected near Detroit from the bark of large Douglas fir (*Pseudotsuga taxifolia*) windfalls;
- 16) *Dryoc. pseudotsugae*, Swaine, not uncommon in the western part of the State; found at Ranier in hibernation galleries in the outer bark of *Pseudotsuga taxifolia*, and under the bark of the same conifer near Olney; also noted at Corvallis and Detroit;
- 17) *Eccoptoraster unispinosus*, Lec., widely distributed in the State, works in *Larix occidentalis*, *Pseudotsuga taxifolia*, and *Picea Engelmanni*; it often causes the death of saplings;
- 18) *Eccoptogaster* n. sp., resembles *unispinosus* in size and form; found in the twigs of a dying *Abies grandis* at Corvallis;
- 19) *Eccopt. subscaber*, Lec., found throughout the State working in *Abies* and especially in *A. grandis*;

- 20) *Gnathotrichus sulcatus*, Lec., common in dying trees, especially in the Western portion of the State. Collected from *A. grandis*, *A. nobilis*, *Pseudotsuga taxifolia* and *Tsuga heterophylla*; noted at Corvallis, Detroit, Astoria, and in the Blue Mountain region;
- 21) *Gn. retusus*, Lec., found on *Ts. heterophylla*, *Pinus contorta*, *P. ponderosa* and *Pseudotsuga taxifolia*; most abundant in the Coast Range and Blue Mountains;
- 22) *Gnathotrichus* sp., on *Alnus oregona* at Florence;
- 23) *Gnathotrichus* sp., on *Acer macrophyllum* at Corvallis;
- 24) *Hylastinus obscurus*, Mannh., a common clover root-borer found in both Eastern and Western Oregon;
- 25) *Hylesinus aculeatus*, Say., not abundant, but bores galleries in *Fraxinus oregona* in the Western valleys of the State; under the synonym of *Leperisinus aculeatus* Lec., a specimen has been found on an unknown host plant at Corvallis;
- 26) *Hyl. aspericollis*, Lec., a rather common species attacking living and dying alder trees (*Alnus oregona*); it usually selects young individuals, but the writer collected a number of adults from old trees near Breitenbush Hot Springs; noted also at Florence and Corvallis;
- 27) *Hyl. granulatus*, Lec., on *Abies grandis* in the Blue Mountains;
- 28) *Hyl. dentatus*, Lec., rare, on *Juniperus occidentalis*;
- 29) *Hyl. imperialis*, Lec. rare, at Corvallis;
- 30) *Hylurgops rugipennis*, Mannh. under the bark of a large dead white pine (*Pinus monticola*) in Santiana national Forest;
- 31) *Hyl. subcostulatus*, Mann., a decided secondary pest entering dying or dead *Pinus ponderosa* after other Scolytids have started their work; especially numerous in this conifer in the Blue Mountain region.
- 32) *Hyl. lecontei*, Swaine, on *P. ponderosa* and *P. contorta* in the Eastern portion of the State, and in the coast variety of *P. comorta* near the mouth of Siuslaw River;
- 33) *Ips emarginatus*, Lec., attacks the cambium of the lower and middle trunk of *P. ponderosa* and *P. contorta*; it excavates large mines often cutting through those of *Dendroctonus valens*, *D. monticolae* and *D. brevicornis* and attacks living, dying and recently dead trees, both standing and fallen;
- 34) *Ips* n. sp., collected from a *Pinus ponderosa* (which had been dead at least 2 years) at Hood River;
- 35) *I. latidens*, Lec., on *P. ponderosa* on Boundry Creek, Grant County;
- 36) *I. radiata*, Hopk., not uncommon in *P. contorta* and *P. ponderosa* in the Blue Mountain Region of Eastern Oregon; collected under bark of drying *P. contorta* in Whitman National Forest;
- 37) *I. rectus*, Lec., reported from Oregon by LECONTE;
- 38) *I. oregona*, Hopk., abundant in galleries in *P. ponderosa*, especially in recently felled trees, at Bend and Ashland;
- 39) *I. pini*, Lec., reported from Oregon by LECONTE;
- 40) *I. interruptus*, Eichl., a single specimen taken from *Picea sitchensis* at Marshfield;
- 41) *I. interpunctatus*, on *Pinus contorta* in the Whitman National Forest;
- 42) *I. concinnus*, Mannh., this species ordinarily attacks *P. contorta* and *Picea sitchensis*; some adults were, however, taken from a fire-injured sapling of *Pseudotsuga taxifolia* at Astoria this was probably an accidental host;
- 43) *I. caelatus* var., on *Picea Engelmanni*, in Grant County;
- 44) *I. confusus*, Lec., on *Pinus*, in the extreme south part of the State;
- 45) *Orthotomicus ornatus*, Swaine, on *Pinus ponderosa* in the Whitman National Forest;
- 46) *Phloeosinus dentatus*, Say., a single example collected from *Chamaecyparis nootkensis*, at Elk Lake;
- 47) *Ph. punctatus*, Lec., found doing considerable damage to *Juniperus occidentalis* in the vicinity of Bend and Prineville, in Central Oregon; galleries of this beetle were also found in *Libocedrus decurrens* on the Klamath Indian Reservation. It has been taken from its galleries

<sup>i</sup>n *Thuja plicata*, *Chamaecyparis nootkatensis* and *Ch. Lawsoniana* in the Western part of the State; the cocoons of an unidentified hymenopterous parasite were found in the mines made by the beetle in *Juniperus*;

43) *Ph. cristatus*, Lec., rare, attacks *Chamaecyparis nootkatensis*, *Abies nobilis* and *Picea Engelmanni*;

44) *Ph. sequoiae*, Hopk., on *Thuja plicata* and *Sequoia sempervirens* in the Southwestern portion of Oregon;

50) *Pseudohylesinus nebulosus*, Lec., particularly on living, dying or felled individuals of *Pseudotsuga taxifolia*; observed in both Eastern and Western Oregon;

51) *Ps. nobilis* Swaine, on *Abies nobilis* in the Cascade Mountains;

52) *Ps. laticollis*, Swaine, found with the above species on *Abies nobilis* and also on *A. lasiocarpa*;

53) *Pseudohylesinus* n. sp., taken in the act of boring into a Lebanon Cedar (*Cedrus Libani*) at Corvallis;

54) *Pseudohylesinus* (an undescribed species allied to *nebulosus* Lec.) taken at Elkington;

55) *Ps. griseus*, Swaine, less common than *Ps. nebulosus*, but in habits, life history, etc., it is very similar; found attacking *Pseudotsuga taxifolia* at Breitenbush Hot Springs in the Cascade Mountains;

56) *Ps. sericeus* Mannh., very similar to the last 2; bred in numbers from *Pseudotsuga taxifolia* collected at Corvallis, Astoria and Detroit, Oregon;

57) *Ps. sericeus* var., bored from *Pseudotsuga taxifolia* at Corvallis.

58) *Pityokiates jasperi* Swaine; two specimens on *Abies grandis* and *A. lasiocarpa*, near Sumpter;

59) *Procryphalus aceris*, Hopk., on *Acer macrophyllum* at Albany;

60) *Tomicus (Hylastes) nigrinus* Mannh., on *Pseudotsuga taxifolia* at Corvallis, Ranier, Astoria and Svensen;

61) *Pityogenes carunculatus* Lec., found attacking living, dying and felled yellow pine (*Pinus ponderosa*) at Bend;

62) *Pityophthorus pubipennis*, Lec., abundant on *Fraxinus oregona* and *Quercus Garryana* in the Western Valleys;

63) *P. puncticollis*, occasionally met with in *Picea sitchensis* and *Pinus contorta*;

64) *P. confusus* Lec.; according to SWAINE, this species is found in Washington and California, so it undoubtedly occurs in Oregon, but the writer has never collected it there;

65) *P. confusus*, Swaine; bred from pine cones collected at West Port, Oregon;

66) *P. nitidulus*, Mannh., a widely distributed species found in dying *Pinus Picea* and *Pseudotsuga*, throughout the State;

67) *Pityophthorus* n. sp., a species similar to *nitidulus*, collected many times from *Abies grandis* in the valleys and from *A. nobilis* in the Cascades;

68) *Trypodendron (Xyloterus) lineatus*, Oliver, from Seaside;

69) *Tryp. (Xyl.) politus*, Say, a single specimen bearing label "Huntingdon Oregon", probably wrongly labelled;

70) *Try. rufitarsis*, Kirby, on *Pinus Contorta* near Sumpter,

71) *Trypodendron* n. sp., near *rufitarsis*, collected on living *Pseudotsuga taxifolia* at Breitenbush Hot Springs;

72) *Xyleborus dispar* Fabr., in orchard trees, at Portland, Salem, Corvallis, Oregon City and Eugene;

73) *Xyleborus xylographus*, Say on *Quercus Garryana* and *Pseudotsuga taxifolia* at Corvallis;

74) *Platypus wilsoni*, Swaine, found on *Abies grandis* at Corvallis; *A. nobilis*, Elk Lake; *Tsuga heterophylla*, Detroit; *Pseudotsuga taxifolia*, Corvallis and Ranier.

- 115 - *Sphinx convolvuli* in England in the Autumn of 1917 (1). — CLARKE, W. J., in *The Naturalist*, No. 731, p. 308. London, December, 1917.

In the autumn of 1917 an immigration of the *Convolvulus Hawk Moth*, was observed in the Scarborough district. The author saw specimens of this moth captured at Scarborough on August 22nd. and September 3rd. 10th. and 12th., together with two others obtained in September, the exact date being unknown. Another specimen was captured at Scalby on August 31st.

- 116 - On the Parthenogenetic Reproduction of *Otiorrhyncus sulcatus*, a Coleopteron Injurious to the Vine, in France. — FETTAUD, J., in *Comptes Rendus des Séances de l'Académie des Sciences*, Vol. 165, No. 22, pp. 767-769. Paris, 1917.

Up to the present the vine weevil (*Otiorrhyncus sulcatus* Fabr.), well known in France for the damage it does to the vine, was considered as having normal sexual reproduction.

The serious attacks made by it in recent years in the Saint-Pierre d'Oléron vineyard (2) gave the author, during the years 1914 to 1917, an opportunity of studying many specimens of this weevil both under natural conditions and in captivity. Among thousands of individuals examined, some of which showed the external characteristics considered proper to the male, the author found none but females.

In May 1917, 50 weevils, collected at the beginning of the season, laid fertilised eggs which gave live larvae, although all the weevils were found to be female.

These observations show the coleopteron in question, like *O. turca* Bohem., *O. cribricollis* Gyll., and *A. ligustici* Linn., to be reproduced generally, if not constantly, by parthenogenesis, thereby adding a fourth species to the three parthenogenetic ones already known. This species is the most common and most harmful of those found in France.

The fact is of great importance from a practical point of view. Since all, or nearly all, the individuals are females, and each lays more than 150 eggs, the annual production is very large in favourable environmental conditions, and the centres attacked spread very rapidly if energetic measures to destroy the pest are not taken.

It is probable that males do exist, but they are doubtless very rare, appearing only sporadically in certain generations.

The parthenogenesis of *O. sulcatus* and its three above mentioned allied species, must be placed, provisionally at least, in the type of irregular parthenogenetic cycle, although the existence of males still remains to be definitely proved.

#### RESISTANT PLANTS

- 117 - A Note on Resistance to Black Scale in Cotton. — HARLAND, S. C., in *West Indian Bulletin*, Vol. XVI, No. 3, pp. 255-256. Bridgetown, Barbados, 1917.

Certain varieties of cotton plant are immune to attack from black scale (*Saissetia nigra* Nietn.). In 1914 many Seredo cottons were introduced into St. Vincent, and showed great differences in their susceptibility to

(1) See also R.-Dec. 1917, No. 1251 — (2) See on this subject B. Nov., 1914, No.

black scale. Two types, remarkable for their resistance, were isolated and cultivated, and, in the following year still showed the same immunity. One of them, carefully studied for three generations, never showed any trace of black scale though the other varieties were badly attacked. The immunity of certain types of cotton is, then, a fixed and transmissible character.

Hybridisation experiments were carried out with the Seredo, a naturally immune variety, and the Sea Island variety, which is very susceptible. The hybrids were quite uniform in their morphological characters, and were almost completely immune to black scale, only a few scattered specimens of the insect being found.

Immunity, therefore, behaves as a partial dominant.

118 - Natural Enemies of *Chrysomphalus dictyospermi*, a Coccid Injurious to Citrus (1). — MALENOTTI, ETTORE, in *Redia*, Vol. XIII, Pt. 1, pp. 17-53, pl. 1-2. Florence, 1917.

MEANS OF  
PREVENTION  
AND CONTROL

The following are mentioned as natural enemies of the coccid *Chrysomphalus dictyospermi* Morg.:

1) a fungus, *Cladosporium* sp., often found in Calabria and Sicily, inside and outside the insect; its importance as a parasite of the coccid has not yet been shown;

2) the mite *Allothrombidium gymnoptorum*, preying actively on the insect in question, on *Diaspis pentagona* Targ. and other *Diaspinae*; it is of no agricultural importance;

3) the native predatory coleoptera: a) *Chilocorus bipustulatus*, L., easily seen on trees attacked by *D. pentagona*, *Aspidiotus hederæ* Vall., *Saissetia oleæ* Bern., and which may also be found on trees attacked by *Chr. dictyospermi*; it is prevented from spreading by the endophagous hymenoptera *Tetrastichus epilachnæ* (Giard.) and *Homalotylus flaminus* (Dalm.); this coleopteron, which has never seriously impeded the development of *D. pentagona* or *Chr. dictyospermi* in Italy, is of great importance in Spain where, in the province of Valencia, a decrease of this last coccid in the orange-groves, corresponds to a great increase of the coleopteron; b) *Exochomus 4-pustulatus* L., which, like the previous one, has three generations each year; c) *Cybocephalus rufifrons* Reitter;

4) the following imported predatory coleoptera: a) *Rhizobius lophantæ* Blaisé; b) *Rhiz. ventralis*; c) *Orcus calibaens*; these have not yet been proved to be of practical importance in the destruction of *Chrys. dictyospermi*.

Then follows a description of 7 chalcid hymenoptera, three of which belong to the sub-family *Eulophinae* and are endophagous:

1) *Aspidiotiphagus citrinus* (Craw.) How., which attacks many species of *Diaspina*, among which are *Aonidia lauri* (Bouché), *Aonidiella aurantia* var *citrina* (Coq.), *A. perniciosæ* (Comst.), *Aulacaspis pentagona*

(1) See also *B. April*, 1911, No. 1312; *B. April*, 1915, No. 451; *B. October*, 1915, No. 1102; *R. July*, 1916, No. 827; *R. August*, 1916, No. 948; *R. October*, 1916, No. 1140; *R. Nov.* 1916, No. 1245; *R. January*, 1917, No. 110. (Ed.).

(Targ.), *A. rosae* (Bouché), *Aspidiotus hederae*, *A. betulae* Baer., *A. destructor* Sign., *Chrysomphalus ficus* Ashm., *Chrys. dictyospermi*, *Hemichionaspis aspidistrae* (Sign), *H. minor* (Mask.), *Lepidosaphes beckii* (Newm.), *Leucaspis signoreti* Targ., etc., but, in Italy at least, the host in which it is most frequently found is *A. hederae*; one of its varieties — *Aspidiotiphagus citrinus* var. *agilior* Berl. — breeds in abundance from *Chionospis euvyni* Comst.; the value of this variety in the control of Diaspinae is not to be despised; in limited areas it sometimes succeeds in checking *A. hederae*, as was the case in the olive orchards of Liguria; but its action is too uncertain for it to be considered always as a means of controlling *A. hederae*; it proved no less efficacious against *A. destructor* on coconuts in the island of Tahiti; *A. citrinus* has been found in *Chrys. dictyospermi* in America since 1904; recently the author found it in the same insect living on *Sansevieria arborescens* in the greenhouses in the Italian Colonial Agricultural Institute at Florence; later, from the coccid of the same *Sansevieria* plant, the author obtained a new *Prospaltella* (*Pr. fasciata*); the percentage (97 %) of *Chrys. dictyospermi* attacked, attributed entirely to *A. citrinus*, must be considered as representing the total action of the two chalcids; it has so far been impossible to determine how much of this total is due to each of the two species; it appears that the proportion of female *Chrys. dictyospermi* attacked by *Pr. fasciata* is fairly high;

2) *A. lounsburyi* Berl. and Paol., does not attack *Chrys. dictyospermi* only; the author also found it in large numbers in *Fiorinia florinae* Targ., on an undetermined plant from Madeira, and at the end of June, 1916, it was found in fairly large numbers on *Diaspis boisduvali* Sign. living on leaves of *Vanilla aromatica* and also, a few days later, on *Hemichionaspis aspidistrae* on a fern of the genus *Nephrolepis*, both in the greenhouses of the Torrigiani garden, at Florence; as regards the value of this chalcid in the control of *Chrys. dictyospermi*, not only were 50% of the specimens of this scale sent by LOUNSBURY from S. Africa attacked, but also scales of other species sent to Florence from Madeira seemed to be attacked by it in large proportion; for this reason it is being distributed by the Royal Station of Agricultural Entomology of Florence.

3) *Prospaltella fasciata* Malen., obtained, as already stated, from *Chrys. dictyospermi* on *Sansevieria arborescens* in the greenhouses of the Italian Colonial Agricultural Institute of Florence with *Aspidiotiphagus citrinus*.

The other four chalcids described belong to the ectophagous species.

1) *Aphelinus chrysomphali* Mercet (sub-family *Eulophyinae*), found by MERCET on *Chrys. dictyospermi* from Spain; the description given by the author is based on two females obtained from *Chrys. dictyospermi* on citrus material sent for study from Spain (Alicante and Palma de Mallorca) and on 70 other females from *Aonidiella aurantii* (Mask.) from gardens in Greece; whereas, according to MERCET this *Aphelinus* is of little practical importance in the control of *Chrys. dictyospermi*, it is very efficacious against *Aon. aurantii* living on lemons and cedrates in Greece (Calamata, Corfu, some islands of the Aegean Sea); in this country it has been noticed that the smell of unburied manure placed under the cedrate tree keeps *Aphelinus*

away, thus allowing *Aonidiella* to multiply; dust which covers the foliage of the trees planted along a road has the same effect.

2) *A. silvestrii* De Greg., the author's description is based on the examination of one female only, obtained near the Royal Station of Agricultural Entomology at Florence from *Chrys. dictyospermi* on orange leaves sent from Palermo by Marquis DE GREGORIO, whose favourable opinion on the practical value of this *Aphelinus* for destroying *Chrys. dictyospermi* is not borne out by observations made at Florence; from many hundreds of the coccid sent by Marquis DE GREGORIO, only one specimen of *Aphelinus* was obtained, and from material, sent by Prof. T. DE STEFANI, also from Palermo, and including fresh leaves of orange, maple and ivy, only two female chalcids were obtained, both from *Chrys. dictyospermi* from maple leaves.

3) *Signiphora merceti* Malen. (sub. family Encyrtinae); two females obtained at Florence on *Chrys. dictyospermi* from Spain, and one female obtained from *Hemiberlesia camelliae* on Robinia from Pietrasanta (Lucca); according to the author this chalcid is not of great importance as a natural enemy of *Chrys. dictyospermi*.

4) *Aphicus hesperidum* Mercet (sub-family Encyrtinae); two male specimens obtained from *Chrys. dictyospermi* from Spain; there is little hope that this chalcid will play a great part in the control of *Chrys. dictyospermi*.

119 - *Phora fasciata*, a Dipterous Parasite of the Coleopteron *Coccinella septempunctata*, in France. — DU BUISSON, H., in *Bulletin de la Société Entomologique de France*, No. 15, pp. 249-250. Paris, 1917.

In July 1912, the author collected in the department of Allier pupae of *Coccinella septempunctata* L., fixed as usual on the upper part of the vine leaves. After having kept them in a small box for a long time, he noticed that one was deformed, and that, near the shreds of leaves near it, were small pupae from which minute diptera had emerged.

In June, 1917, the author again collected in the same department pupae of *C. septempunctata* fixed, well in evidence, on potato leaves, and put aside 37 specimens in perfect condition. Of these, 33 emerged normally towards July 12th., but the 4 others were deformed, and near them, on the leaf on which they lay, were again dipterous pupae. These were placed for observation in a tube and the perfect insect emerged after July 12th.

DR. J. VILLENEUVE, who examined the dipterous, identified it as *Phora fasciata* Fallén, adding that RONDANI (*Atti Soc. ital. Sc. nat. Milano*, II [1860], p. 165) had already published a note describing this species as a parasite of the pupae of *C. septempunctata*.

120 - *Sycosoter lavagnei* n. g. and n. sp., a Hymenopterous Parasite of the Coleopteron *Hypobarus ficus*, Injurious to the Fig Tree, in France. — PICARD, FRANÇOIS and LICHTENSTEIN, JEAN L., in *Bulletin de la Société Entomologique de France*, No. 16, pp. 284-287, figs. 1-3. Paris, 1917.

The breeding-out of the scolytid *Hypobarus ficus* Erichs, from the branches of the fig-tree, at Montpellier, gave a braconid parasite described here

as a genus and species new to science under the name of *Sycosoter lavagnei*.

This insect is an external parasite of the larva of *Hyp. ficus*. The egg is placed on the host through the bark of the fig tree. The larva spins a cocoon in the gallery of the scolytid for pupation. It appears that *Syc. lavagnei* has as many generations as *Hyp. ficus*. The spring females of the hymenopteron are almost all winged; those of the autumn are chiefly apterous. Winged males seem rarer than apterous ones, even in spring.

INSECTS, ETC.,  
INJURIOUS  
TO VARIOUS  
CROPS

121 - *Phytoecia cylindrica*, a Coleopteron Injurious to Carrots, in Sweden. --

KEMNER, N. A., in *Meddelande No. 139 från Centralanstalten för Försäkränsändel* Jordbruksomr del, *Entomologiska Afdelningen*, No. 26, pp. 1-8, fig. 1-8. Stockholm.

In the autumn of 1915, the cerambycid *Phytoecia cylindrica* L. ("Stjälkbocken") was reported to be damaging seed carrots near the Stockholm Agricultural Experiment Station.

The larvae of the insect, at a certain distance above the soil, enter the stalk and bore within it long galleries down to the roots, thus preventing the normal development of the plant. The insect influences not only the quantity of seed produced, but also the quality. In the case in question the percentage of seeds capable of germinating fell as low as 30.

This insect is found in the north of Sweden, as far as Stockholm, and in Västmanland. It is also fairly common in Norway and Finland.

122 - *Rhagoletis pomonella*, the Apple Maggot, or Railroad Worm, an Injurious Dipteron Recorded for the First Time in British Columbia, Canada (1). --

TREHERNE, R. C., in *The Canadian Entomologist*, Vol. XLIX, No. 10, pp. 329-330. London, 1917.

Two adult flies of *Rhagoletis pomonella* Walsh (fam. *Trypetidae*) were taken by the writer near Penticton (British Columbia), on July 16, 1916. The fact is interesting, for this is practically the first time this insect, which attacks apples, has been recorded in the province of British Columbia, and it is practically the first time that it has been mentioned as occurring on the Pacific Coast of North America.

The flies were taken on the Red Astrachan variety of apple, but examination of its fruit and those of other early varieties in the vicinity on July 26th. and again in August, revealed no definite sign of larval injury. Many early varieties of apple had been picked and shipped at the time of this second examination. Consequently, this fact, coupled with the lateness of the season, which was towards the end of the flight period of the adults, probably accounts for the paucity of material.

As regards the distribution of this species of fly on the Pacific coast, 5 specimens were collected by O. T. BARON in the southern part of California, and described by SNOW in 1894 as *Rhagoletis zephyria* n. sp. R. W. DOANE in 1908, and J. M. ALDRICH in 1909, stated that *R. Zephyria* is a synonym of *R. pomonella*. Since the record of 1894, apparently this insect has not been observed again in California.

According to information furnished to the writer by ALDRICH, the insect has been recorded from the eastern slope of Colorado (Colorado Springs, Fort Collins).

No information is available that the species exists in the State of Oregon, but A. L. MELANDER states that it has been recorded as destructive along the eastern border of the State of Washington. He remarks, however, that there is no positive evidence of its occurrence in Washington orchards.

Consequently, the record for British Columbia is almost unique for the Pacific Coast. Evidently the insect is not yet numerous in British Columbia, otherwise its presence would have been observed before. Even yet, no definite form of larval injury has been observed, and the record, thus far, exists only in the form of the capture of 2 adult flies. It is interesting to note, however, that E. H. STRICKLAND captured a single specimen of this fly at Lethbridge (Alberta) in 1914. These are little doubt that the insect emerged from imported fruit, and as the Province of Alberta is supplied more commonly with western fruit than with eastern, the record suggests an interesting probability.

123 - *Stomacoccus platani* n. gen., and n. sp., A Coccid Observed on *Platanus racemosa* in California. — FERRIS, G. F., in *The Canadian Entomologist*, Vol. XLIX, No. 11, pp. 375-378 + figs. 36-39. London, November, 1917.

This paper gives a systematic description of the new genus *Stomacoccus* and the new species *St. platani* together with information on the biology of the coccid.

The insect was found in California on leaves, branches and trunk of *Platanus racemosa* (sycamore) at Pasadena, Stevens Creek (Santa Clara County) and near Stanford University.

124 - Cynipidae Observed on *Castanopsis* spp. and *Quercus* spp. in America. — BEUTENMULLER, WM., in *The Canadian Entomologist*, Vol. XLIX, No. 10, pp. 345-349. London, October, 1917.

This paper gives a systematic description of the following gall-forming hymenoptera :

1) *Andricus castanopsidis* n. sp., on flowers of western chinquapin (*Castanopsis sempervirens* and *C. chrysophylla*), in the following districts of California : Pacific Grove (Monterey County), Truckee, Mount Tamalpais, Placer County ;

2) *A. myrtifoliae* n. sp. on flowers of *Quercus myrtifolia* at Jacksonville and Palatka (Florida) ;

3) *A. gemmiformis* n. sp. on the trunk of *Q. alba* in the district of Fort Lee (New Jersey), at Woodlawn (New York City), at Evanston (Illinois) ;

4) *A. dugesi* n. sp. at Guanajuato (Mexico) ; the gall produced by this species was not observed ;

5) *Biorhiza caepulaeformis* Beutenmuller, at the base of shoots of *Quercus rubra* at Evanston ;

6) *Amphibolips nigra* Beutenmuller, on branches of *Quercus* sp. at Durango (Mexico) ;

7) *Dryophanta floridensis* n. sp., on the trunk of Spanish oak (*Q. pigitata*) and Blue Jack (*Q. brevifolia*), at Ocala and Jacksonville (Florida).

GENERAL INFORMATION.

- 125 The Distribution in Wheat, Rice and Maize Grains of the Substance, the Deficiency of which in a Diet causes Polyneuritis in Birds and Beri-beri in Man. — CHICK, HARRIETTE and HUME, E. MARGARET, in *Proceedings of the Royal Society*, Series B. Vol. LXXX, No. B. 624, pp. 44-68. London, December 1, 1917.

RURAL  
HYGIENE

The experiments described were carried out at the Lister Institute, and the results obtained led to the following conclusions: —

Wheat endosperm, which constitutes white flour, is deficient in anti-neuritic vitamins (the substance whose deficiency in a diet causes polyneuritis in pigeons and beri-beri in man) (1); when fed to pigeons as an exclusive diet it caused polyneuritis in a manner identical with polished rice.

In both the wheat and rice grain, the anti-neuritic vitamin is concentrated mainly in the germ or embryo; it is present in less quantity in bran (pericarp and aleurone-layer), probably in the aleurone-layer. The embryo of maize grain also possesses marked anti-neurotic properties, both in the scutellum and in the plantlet. For this reason it is important to include the germ in the flour from which wheaten bread or biscuit is made, especially when the diet may consist largely of preserved foods, which are deficient in the vitamin.

The daily ration of wheat-germ that must be added to a diet of polished rice in order to prevent the onset of polyneuritis is equal to the amount which, administered by the mouth, will cure a pigeon acutely ill with polyneuritis, brought on by an exclusive diet of polished rice. This relation is not peculiar to wheat germ, but applies to other foodstuffs, such as yeast, containing anti-neuritic vitamins. The addition of wheat-germ to a diet of polished rice in quantity (3 gm. every second day) sufficient to prevent

(1) See R. Jan., 1918, No. 2, (Ed.).

polyneuritis, also maintained the weight and general health of the bird. Rations in excess of this (2 to 3 gm. every day) led to a great increase in body-weight and in the general well being and vitality of the birds.

Exposure of wheat embryo to a temperature of about 100° C. for two hours caused an insignificant loss in anti-neuritic vitamine; therefore, if it be included in the flour from which bread or biscuit is made, it can be relied upon to retain its anti-neuritic properties after baking.

At temperatures in the neighbourhood of 120° C., however, there was a swift destruction of anti-neuritic properties. This fact must be borne in mind in dealing with diets largely composed of preserved and tinned foods previously sterilised at temperatures above 100° C.

126 — Some Remarks on Macedonian Anopheles. — COT and HOVASSE, in *Bulletin de la Société de Pathologie Exotique*, Vol. X, No 10, pp. 890-896 Paris, December 12, 1917.

Macedonia, together with Greece, is the worst malarial district of Europe. The authors examined: — 1) the nature of Anophelines and their larvae; 2) their life cycle and the influences modifying it; 3) the percentage of Anopheline carriers of hematozoa. Their observations showed the following interesting points: —

The principal carriers of malaria in the Salonica district are *Anopheles maculipennis* and a special variety of *Pyretophorus superpictus* which it is proposed to call *P. macedoniensis*.

The life cycle varies greatly, especially the larval stage, and is largely dependent on the temperature. Contrary to the opinion generally held, an altitude of 1956 to 3260 feet (Mount Hortiack), as well as a decrease of 10° C. at night, are not sufficient to stop evolution. It seems that the Anopheles of Salonica are adapted to the great variations of day and night temperature characteristic of the country.

The proportion of Anopheles found to be infected was 8 %; they were found especially at Mikra where the cases of malaria were very frequent in proportion to those found elsewhere.

#### AGRICULTURAL EDUCATION

127 — Agricultural Education in the United States. — FORRITT, EDWARD, in *The Quarterly Review*, No 453, pp. 315-333 London, October, 1917.

The Department of Agriculture at Washington has been a department of first rank in the executive branch of the Government of the United States — a department presided over by a Cabinet Minister — since 1889. In these 28 years it has gradually acquired one outstanding distinction. With the single exception of the Post Office, it is to-day in more close and frequent touch with the hundred million inhabitants of the United States and it renders them more constant and direct service, than any other department of state at Washington.

This article is concerned only with the educational work of the Department of Agriculture. The simplest method of describing the work of Congress and of the Department on behalf of good agriculture and efficient farm economy is to take the budget of one of the state agricultural colleges, and show the connection of Congress and the Department with the 66 agricultural colleges and with the farm experiment stations associated with the

colleges, and the connection of the colleges and the Department with the vast scheme of educational extension work now being carried out under the Smith-Lever Act of 1914.

The budget of the agricultural college of the State of Illinois, for the year 1916-1917, shows that it received grants from the Federal Government towards the cost of its maintenance under three heads :

1) For the endowment of teaching in agriculture and the mechanic arts (MORRILL and NELSON funds) annually. . . . .	\$50 000 000
2) For investigation in agriculture (HATCH and ADAMS funds) . . . . .	30 000 000
3) For demonstration work in agriculture and home economics (SMITH and LEVER funds, 1916-17) . . . . .	58 184 030
Total . . .	\$138 184 030

In some states there is more than one agricultural college. The total number in 1917 was 66. In 1857 the first bill passed by Congress for aiding the state governments to establish colleges for the teaching of agriculture was vetoed by President BUCHANAN. The bill had been introduced by J. S. MORRILL, of Vermont. Four years later, after the election of LINCOLN, and of a new House of Representatives, MORRILL reintroduced his bill. A similar bill was introduced in the Senate; and in June 1862 there was enacted the law under which what have since been known as the Land Grant Colleges came into existence.

The Federal Government at that time had enormous areas of public land at its disposal; and, with money accruing from these lands, the agricultural colleges, now under the control of the state governments, were founded. By the Act of 1862 each of the then existing states received from the Federal Government a large donation of public land. Representation in the Lower House at Washington is based on population; and under the Morrill Act there was apportioned to each state an area of land equal to 30 000 acres for each senator and representative in Congress to whom the state was entitled by the apportionment under the census of 1860. As the lands so assigned were sold, the money accruing was directed by the Morrill Act to be invested in bonds of the United States or in state bonds. The money was to form a perpetual fund; and the interest accruing from it was to be applied to the support and maintenance of at least one college in each state,

"where the leading object shall be, without excluding other scientific and classical studies, and including military tactics, to teach such branches of learning as are related to agriculture and the mechanic arts, in such manner as the legislatures of the states may respectively prescribe, in order to promote the liberal and practical education of the industrial classes in the several pursuits and professions of life".

By the Morrill Act, and also by four subsequent Acts for aiding the states in promoting the teaching of agriculture, the cost of buildings for agricultural colleges has always been a charge on the states.

Over agricultural colleges established under the Morrill Act the Federal Government had no supervision or control. It was left to the state

legislatures to prescribe the course of teaching. There was no audit in the interest of the Federal Government, no examination, test or inspection to ascertain whether the Federal Government, as representing the people of all the states, was getting value for its money. All the duties of a state government to the nation outside its own borders in respect to its agricultural college, largely maintained by the Federal Government, had been discharged when copies of the annual report of the college, "recording any improvement and experiments made, with their costs and results", had been forwarded to the Secretary of the Interior at Washington, and also to all the other colleges endowed by the land grants of 1862.

Between 1862, when the Federal Government made possible an agricultural college in every state, and 1914, when the Smith-Lever Act was passed, three additional grants were made to the State agricultural colleges for the extension of their work. The first was in 1887. Congress then passed an Act providing for the establishment of agricultural experiment stations in connection with the agricultural colleges. A grant of \$15 000 a year was made to each state for the maintenance of an experiment station. The work to be undertaken was defined in the Act as follows :

"To conduct original researches or verify experiments in the physiology of plants and animals; the diseases to which they are severally subject, with remedies for the same; the chemical composition of useful plants at their different stages of growth; the comparative advantages of rotative cropping, as pursued under a varying series of crops; the capacity of new plants or trees for acclimation; the analysis of soils and water; the chemical composition of manures, natural or artificial, with experiments designed to test their comparative effects on crops of different kinds; the adaptation and value of grasses and forage plants; the composition and digestibility of the different kinds of food for domestic animals; the scientific and economic questions involved in the production of butter and cheese; and such other researches or experiments bearing directly on the agricultural industry of the United States as may in each case be deemed advisable, having due regard to the varying conditions and needs of the respective states or territories".

It was under this law of 1887 that, for the first time, the Department of Agriculture at Washington was brought into direct connection with the work of the agricultural colleges. The connection was effected by a section of the Act which directs that, in order to secure, so far as possible, uniformity of methods and results in the work of the experiment stations, it shall be the duty of the Secretary of Agriculture to furnish forms for the tabulation of the results of investigations or experiments; to indicate from time to time such lines of enquiry as shall seem most important to him; and in general to furnish such advice and assistance as will best promote the purpose of the Act.

A few years afterwards, the American Association of Agricultural Colleges and Experiment Stations was organised; and, chiefly at the instance of this association, Congress in 1906 increased the appropriation for each experiment station from \$15 000 to \$30 000 a year. Earlier than this — in 1890 — by the Nelson Act, an additional annual appropriation was made to each of the agricultural colleges. The net result of these Acts of Congress of 1862, 1887 and 1906, for the advancement of the teaching of agriculture,

was that in 1914 — the year before the Smith-Lever Act — each state was receiving from the federal treasury \$50 000 a year for its agricultural college, and \$30 000 for its experiment station.

Since in all this legislation the cost of the buildings at agricultural colleges and at experiment stations, with their maintenance and repair, is thrown on the state and all the state legislatures make annual appropriations for their colleges, it will be realised that this liberal expenditure in the interest of agriculture by federal and state governments has popular support.

In these years, before the United States Government made appropriations to the states for extension work, there existed in the Department of Agriculture a division which was exclusively concerned with the work at the State experiment stations. Its functions, which since the Smith-Lever Act came into operation have been taken over by the States Relation Service Bureau of the Department, were to carry out the provisions of the Acts of 1887 and 1906; to enable the Secretary of Agriculture to certify to the treasury department when federal grants might properly be paid to the state experiment stations; to report to Congress regarding the work and expenditures of the stations; and to aid the stations in the effective development of their work.

Inspectors from the bureau visit each experiment station at least once a year. Its work and its expenditure are carefully examined; and on the basis of reports made by these inspectors, warrants are issued on the United States treasury for the payment of the grants to the various states. Stations must submit their schemes of work to the Secretary of Agriculture, practically to the States Relations Services Bureau.

While the agricultural colleges were extending their work by means of the federal grants of 1887, 1890 and 1906, and of liberal appropriations from the state legislatures, larger appropriations were made by Congress to the Department of Agriculture, and its work was greatly extended. The appropriation for the Department for 1887-1888, the year in which Congress made its first grant to the colleges for experiment stations, was \$637 000. Ten years later, in 1898-1899, the appropriation had risen to nearly \$2 500 000. In 1908 it was nearly \$10 000 000; and for 1913-14, the year before the Smith-Lever Act came into operation, it was \$16 651 000.

With the enactment of the Smith-Lever law the Department entered on a new era. It began to have a direct, as distinct from an indirect part in what may be described as the popular teaching of agriculture and farm economy. From 1887 to 1914 its work for agricultural education was, in the main, done through the state experiment stations and by means of bulletins and reports sent through the post to farmers, cotton growers, grain growers, cattlemen, foresters and lumbermen, market gardeners, fruit growers, and poultry men. The most widely-circulated of the Department's publications is the "Farmers' Bulletin". The bulletins are written in plain language, and are adapted to the different sections of the country, 'their specific object being to tell farmers how and when to do things'; in 1914 in the aggregate 14 795 000 bulletins were sent through the mails. What are known as Department Bulletins are more specialised than the

Farmers' Bulletins. They are concerned with subjects of interest to fruit growers, truck growers (*i. e.* market gardeners), poultry men, and lumbermen. They are intended for men who are specialists, actively engaged in these various industries, and who, while not technical men, can be described as professional workers. Included in the Department Bulletins are what are known as Professional Papers, in which information on highly technical subjects is communicated to scientists or technologists in the same or allied fields of enquiry. These bulletins are issued in editions averaging six thousand copies. They are distributed free to applicants.

Purely scientific and technical subjects are handled in the "Journal of Agricultural Research", which is issued weekly, and is sent free to the agricultural colleges and experiment stations, and to technical schools and universities.

The "Experiment Station Record" is a technical review of the world's scientific literature pertaining to agriculture. Its free distribution is restricted to the staffs at agricultural colleges and experiment stations. The "Weekly News Letter" is a quarto sheet of four pages, three columns to a page. It contains news of the more important activities of the Department, with articles on farm practice and home economics. Its circulation is restricted to the employees of the Department in Washington and in the field, to crop correspondents, and to various agencies that cooperate in the work of the Department. The "Monthly Crop Report", distributed to all persons sufficiently interested to ask that their names should be placed on the mailing list, publishes data concerning current agricultural conditions. Its chief features are estimates of acreage, reports of conditions and statistics as to yields and prices. At the end of each month comes the list of publications. It gives a brief description of each publication issued during the month, and an indication of the region of the country to which it is adapted. It is by means of this list that miscellaneous applicants are enabled to keep in touch with the Department and to ask for those publications in which they are interested.

The duties and functions of the Department between 1887 and 1914 came to include much that might not inaptly be described as police work, chiefly in connexion with the administration of the federal pure-food code, the stamping-out of disease among cattle, and the eradication of insects and diseases that work havoc in the plant world. But it was chiefly through its supervision of the work of the state experiment stations and through its various widely-circulated publications, that the Department made its contribution to the propaganda for improved farming and better economic and social conditions in the farming communities.

For some years before the new era in the history of the Department, which began after the passage of the Smith-Lever Act, several of the larger agricultural colleges, with some help from semi-public organisations like the Rockefeller Foundation, or from chambers of commerce, or from state associations for the improvement of agriculture, had been engaged in extension work. The college faculties had organised itinerant schools for the teaching of agriculture. Not content with the work they were doing with

their four-year students or their short-course students they had sent their teachers into the rural communities, where they conducted schools for even as short a period as two weeks and then moved on to another community. In a considerable number of states county agencies had also been established. Graduates of agricultural colleges, after they had had two or three years of actual experience on farms, were, if suitable, appointed resident county agents at salaries from \$1200 to \$1800 a year, and commissioned to devote the whole of their time to visiting farms, instructing farmers in new and improved methods of work, and in improving the general farm economy of the counties in which they are placed.

Women graduates of the agricultural colleges who had specialised while at college in the care of poultry and in farm economy were similarly appointed, to devote their time to the education of the women of the farms in matters pertaining to farm home management.

It was found, as early as 1912, that this extension work by the agricultural colleges was highly appreciated in the farming communities of the states in the south and west in which it had been undertaken. It was perceived that this direct teaching was resulting in more efficient farming, and finally that it was obviously tending to make farm life more attractive to the boys and girls of the farms. It was also realised at Washington that colleges which embarked in this direct teaching of agriculture and farm economy should not be dependent on semi-public sources for the funds with which to carry it on, but that it was a mission in which the Department of Agriculture should have some part, and over which the Department should have some supervision, as since 1887 it has had over the State experiment stations.

Under the Smith-Lever Bill a grant of \$10 000 a year is made to each of the states for extension work, and a second grant, based on the rural population of the state, is made subject to the condition that a corresponding grant for extension work is made by the state legislature. For the year 1916-17 the total grant was \$1 580 000. Each year until 1921 the grant will be increased; and, when the maximum is reached, a little over \$5 250 000 a year from the federal treasury will be available as the contribution of the Federal Government towards the cost of the extension work of the state colleges of agriculture.

The Bill proposed to set up a system of general demonstration teaching throughout the country, while the agent in the field of the Department and the college was to be the mouthpiece through which this information was to reach the people — the man and woman and the boy and girl on the farm. The plan proposed undertook to educate the farmer by personal contact — by going on to his farm, under his own soil and climatic conditions, and demonstrating that there are methods which in results surpass his own.

The problems with which the Department of Agriculture and the teachers of agriculture and farm economy are confronted are various. Among these are the one-crop areas; the large proportion of farmers who are owners of the land they cultivate, but make a poor living and have little money at their disposal; the chronic shortage of labour in all farming communi-

ties; the large number of farms in the hands of new-comers from European countries who cannot read English; and the large areas in the southern cotton-growing states, where tens of thousands of small plantations — one-mule farms — are rented by negroes.

The Smith-Lever law came into operation in the fiscal year 1914-15. Some details of its working were given to the committee of agriculture of the House of Representatives by Mr. C. B. SMITH, chief of the Office of Extension Work, one of the subdivisions of the States Relation Service Bureau of the Department as follows: —

“The department and the college employ a state leader who is in charge of all county work. The state leader selects the county agent, inaugurates and directs his work, subject to the approval of his superior officers, who are the director of the Extension Service and the director of the States Relation Service in the department at Washington. The state leader has to find men who understand the science of agriculture and the practice of agriculture. He takes graduates of the colleges who have remained in the state, and who have made a success in the practice of agriculture. He takes the agent down to the county where he is to be employed, and lets the people look him over, and see whether or not he is acceptable to them. His employment is the joint action of the county, the state, and the Department of Agriculture. The county agent's business is to bring to his county everything that is appropriate to that locality. If the farmers need a cow-testing association, he will help them to organise it. If they need a breeding association, he will help them with it. The one big thing that he needs... is to have a good organisation of farmers behind him, supporting him in his work, and helping him to shape up the work itself”. The agent also introduces new and better varieties of seed, as well as improved cultural methods, etc.

Extension work with the women on the farms in the south was begun in 1910. In 1915 there were 350 women county agents at work in the southern states. They deal with the problems of the farm and farm economy. They teach home-gardening, the canning of fruits and vegetables from the gardens; they give demonstrations of labour-saving devices in the home — home-made affairs — leading to better conditions and greater economy in the home itself. “Women county agents are to-day reaching approximately thirty-five thousand homes in the south”.

A new value attached to the work and opportunities of the county agents as soon as the United States became involved in the war. In the agents both the Department of Agriculture and the agricultural colleges had a ready medium through which farmers and food-growers could be directly reached and immediately interested in the new movement. Local committees secured land in or near the cities for free allotments; and through the work of these committees, lawns were broken up for vegetable gardens. County agents, and supervisors working under them gave instruction on the spot to the amateur gardeners, and in many places they also helped them in securing seed and fertilisers.

In the fiscal year 1916-17 approximately \$34 000 000 were being expended by the Government of the United States on the Department of Agriculture, on the agricultural colleges and experiment stations, and on extension work under the Smith-Lever Act.

Appropriation to the department of agriculture . . . . .	\$25 000 000
MORRILL and NELSON funds for colleges of agriculture. . . . .	2 400 000
HATCH and ADAMS funds for experiment stations . . . . .	1 440 000
SMITH-LEVER Act. . . . .	1 580 000
MEAT inspection . . . . .	3 000 000
Printing funds . . . . .	600 000
Total . . .	\$34 020 000

The Department of Agriculture serves the urban communities in at least two ways. The inspection of all food products that enter into interstate commerce — all food products that are marketed outside the states in which they are grown and prepared for sale — comes under the Department. Many such products cannot be sold unless they bear the stamp of the Department. The urban population also shares, or can share, with the rural population in that part of the extension work which is devoted to home economics; and largely through the activities of the Federation of Women's Clubs, home economics are now being systematically studied by women in the cities. But in normal times no part of the propaganda of the Department is directed to persuading people to leave the cities in order to engage in farming. The object of the Department and of the agricultural colleges and the extension work is the same — to improve all departments of farm economy, to improve conditions on the farms and in the farm homes, and thereby to retain in rural pursuits the men, women and children who are now on the six million farms of the United States.

## CROPS AND CULTIVATION.

- 128 - *The Relation of Movement of Water in a Soil to its Hygroscopicity and Initial Moisture* (1). — ALWAY, F. J. (Chief of Division of Soils) and MC DOLE, G. R. (Assistant in Soils, Agricultural Experiment Station of the University of Minnesota), in the *Journal of Agricultural Research*, Vol. X, No. 8, pp. 391-428, XX tables, 2 fig. + bibliography of 17 publications. Washington, August 20, 1917.

A short, historical review of the subject is given. Much work (TROMMER, VON LIEBENBERG, VON KLENZE, EDLER, WOLLNY, KRAKOW, GREBE, RAMANN, BRIGGS and LAPHAM, etc.) has been done on the upward movement,

SOIL PHYSICS,  
CHEMISTRY  
AND  
MICROBIOLOGY

(1) See B. 1914, No. 308; R. 1916, No. 8; R. 1917, No. 1114. (Ed.)

or capillary rise, of water, and the relation between its rate and distance and the texture of the soil; the results have shown that the finer the texture, the slower is the rise at first, but the greater the final distance reached. On the other hand, up to the present, the downward movement, or infiltration of the water, and the relation of its rate and distance to the texture of the soil, has been studied by a few workers only (VON LIEBENBERG ATTERBERG, WOLLNY, etc.). The results obtained are too discordant to justify definite conclusions, and usually refer only to coarse soils of low hygroscopicity; the relative hygroscopicity of the soils was never taken into consideration. Under natural conditions, in the moist region, the moisture content of the surface foot of soil is rarely as low as the hygroscopic coefficient ( $x$ ) and, in semi-arid regions, it rarely falls below this value.

The experimental conditions, then, were not in accordance with those found in nature. For this reason the authors undertook new experiments on the upward and downward movement of water, taking into account the hygroscopicity of the soils as expressed by their hygroscopic coefficients and their initial moisture. Seventeen soils, chosen for their different compositions, ranging from coarse sand (hygroscopic coefficient = 0.6), to a silt loam (hygroscopic coefficient = 13.3), were placed in three different degrees of moisture, corresponding to 0.5, 1.0 and 1.5 times the hygroscopic coefficient. The first condition corresponds to the lower limit of moisture in exposed surface soils after a prolonged drought during hot weather, the second to the condition found just after the ripening of a very heavy crop during warm, dry weather, the third corresponds to the wilting coefficient (BRIGGS and SCHANTZ) (1).

I. DOWNWARD MOVEMENT IN SOILS OF DIFFERENT INITIAL WATER CONTENT. — *Method*: — To bring the soils to the desired moisture content, air-dried material was shovelled over on oilcloth, the calculated amount of water being added meantime. The whole was then passed through a swing sieve, again shovelled, then placed immediately in a large, covered can, where it was left for several days. It was then again passed through the sieve, and returned to the can till needed for the experiment, when it was put into glass cylinders 36.2 cm. high and 7.8 cm. in internal diameter. In filling the cylinders, the soil was well pressed down while it was being put in. One inch of water was then added to the surface. To make the initial penetration more uniform, the cylinders were inverted in flat-bottomed trays, the desired amount of water added and allowed to rise into the soil by capillarity, until all, or nearly all, had been absorbed. The cylinders were then placed right side up, covered to prevent evaporation and protected from the sunlight.

The rate of penetration was observed during 5 days, the depth of the water being marked in pencil on the cylinders at intervals of 1, 3 and 24 hours. (More than one cylinder was used for each soil as a means of control, but, as the results coincided so well, only the averages are given). At the end

(1) For this term, see B. 1912, No. 903. (Ed.)

of the period of observation, the soil was removed from the cylinders, the moist part divided equally into three, and the moisture determined.

The results led the authors to the following conclusions, shown in the many tables given.

1) *Relation of the apparent specific gravity and the hygroscopicity.* — Fine-textured soils show a lower apparent specific gravity than the coarser ones, but no direct relation was found between groups of similar texture.

2) *Relation of water retentiveness to maximum water capacity.* — The value of the maximum water capacity is of little significance in the determination of water retentiveness. At the end of 1 hour, the moisture content is only from  $\frac{1}{2}$  to  $\frac{2}{3}$  of the maximum water capacity.

3) *Rapidity of change of moisture content in the moistened layer.* — The moisture content falls more rapidly with finer-textured soils; after 24 hours it is only 2 or 3 times the hygroscopic coefficient, while in coarser soils it varies from 5 to 10 times this coefficient.

4) *Relation of the rapidity with which equilibrium is attained to the hygroscopicity.* — The coarser the soil the more slowly is equilibrium reached; at the end of 5 days equilibrium had practically been attained in the finer-textured soils; this was far from the case in the coarser ones.

5) *Relation of hygroscopicity and the initial moisture on the one hand, and the rate and depth of penetration on the other.* — The rate of penetration depends little upon the hygroscopicity, but varies very much with the initial moisture, increasing in rapidity with an increased moisture content. The same applies to the depth of penetration, which is not closely related to the hygroscopicity, but depends greatly on the initial content; the depth of penetration increased with the moisture content during the 5 days.

6) *Relation of water content of the moistened layer to initial moisture.* — There is no distinct relationship for the finer-textured soils, but, with the coarser soils, the drier the soil, the wetter is the moistened layer.

It follows that, if rain is preceded by a period of high evaporation, the weather immediately following this rain will have a greater influence upon the loss of moisture by evaporation in the case of a coarse than of a fine-textured soil, as a result of the tardiness with which equilibrium is reached in the coarse soils.

II. UPWARD MOVEMENT IN SOILS OF DIFFERENT INITIAL MOISTURE CONTENT. — *Method:* — The same soils, in the same state of moisture (*i. e.* 0.5, 1.0, 1.5 times the hygroscopic coefficient), were used as in the previous experiment, and placed in tubes 160 cm. long and 3.0 cm in internal diameter. The soil was well packed, either by jarring the tube while the soil was added through a funnel, or else compressed with a rubber stopper on a wooden rod, passed through the metal funnel connected with the tube. The first method was used for soils the moisture content of which was 0.5 and 1.0 times the hygroscopic coefficient, the second for those 1.5 times the hygroscopic coefficient. The tubes were then placed upright in a rack, the lower end of each dipping into a metal trough and resting on a strip of 0.25 inch mesh wire netting, the object of which was to prevent both the entrance of water and the escape of air. Throughout

the experiment the water in the trough was kept at a depth of 1.5 inches. The experiments with soils of a content equal to 0.5 and 1.0 times the hygroscopic coefficient lasted 10 days, those for the other soils, 8 days. The height of rise was observed at the end of 1, 2, 3, and 24 hours during the first days, and then at the end of each 24 hours. At the end of the period the moisture in the uppermost layer of the moistened portion of the soil column was determined.

The results obtained led to the following conclusions: —

1) *Influence of the method of compressing the soil on the capillary rise.* — The jarring and compression methods have no influence on the soils in the driest condition; in the moist soils the compression method seems to retard the rise, at least during the first 24 hours.

2) *Relation of hygroscopicity to the rate and height of the rise.* — There is no definite relation; if, at the beginning, the rise is more rapid in soils of low hygroscopicity, this difference gradually disappears.

3) *Relation of initial moisture content to the rate and height of the rise.* — No definite relation was seen; in the three moisture conditions studied the rise was generally most rapid in the moistest and slowest in the intermediate.

4) *Distribution of moisture in the soil columns.* — All the finer-textured soils show the highest percentage of moisture at the top of the wet layer when used in the driest condition, but the coarser soils show no regularity. In soils other than sands, the moisture content of the wet layer is in close relation to the moisture retentiveness. From this it may be concluded that the wet layer has a moisture content equal to the moisture coefficient, *i. e.* from 1.7 to 2.5 times the hygroscopic coefficient.

III. — *RELATION OF PENETRATION TO CAPILLARY RISE.* — If the soils be arranged in order of the rate and depth of penetration and of the capillary rise, the relative positions of the various soils show no similarity. In other words, the relative rates and differences of penetration in the different soils are not similar to the relative rates and heights of capillary rise (this lack of similarity was shown by VON LIEBENBERG in his studies on dry soils).

Some of the soils used contained 3 and 4 times as much organic matter as the others. No characteristic relation was observed between the variation in organic matter and the rate and height of penetration; but the organic matter increased the capillary rise after the first day and the height attained in all the three moisture conditions studied.

129 — *Further Studies on the Nitric Nitrogen Content of the Country Rock.* — STEWART, R. and PETERSON, W., in *Utah Agricultural College Experiment Station, Bulletin No. 150*, pp. 20, 1 fig., VII tables. Logan, Utah, May, 1917.

Certain soils in western America contain spots very rich in nitric nitrogen, having often a nitric nitrogen content several hundred times higher than that of normal cultivated, irrigated soil. These are locally known as "nitre spots". Two theories have been expressed with regard to the origin of these accumulations: — 1) that of HILGARD, who attributed it to the more rapid nitrification of the organic matter of the soil in arid climates;

2) that of HEADDEN and SACKETT, who attributed it to the fixation of the atmospheric nitrogen by non-symbiotic bacteria.

Experiments made during 10 years by the authors on the influence of irrigation water on the production and movement of nitrates in irrigated soils, led them to form an entirely different opinion as to the origin of these nitre spots. They consider them to result from the leaching of the nitrates out of the pre-existing deposits in the rock and their local concentration by seepage water.

Two facts contributed to the formation of this opinion: — 1) it was found that nitrification is not appreciably more rapid in arid soil than in humid soil when measured by the nitrates present in the soil at various depths, in definite seasons and from year to year; 2) all the data supplied by HILGARD and HEADDEN on nitre spots, always mention additional amounts of other alkali salts.

Previous work had already shown that rock adjacent to the affected areas which had contributed to the soil formation, was impregnated with alkali salts, including nitrates, and in sufficient abundance to account for the accumulations noted. The investigations were continued with respect to various soils belonging to three geological formations — jurassic, cretaceous and tertiary. All cretaceous soils were found to contain nitrate. Tertiary soils contain slightly less, although it is in them that are found the greatest number of nitre spots. Jurassic formations have a much lower nitrate content (See Table I).

Analyses were made of soils from different parts of Utah, belonging not only to the cretaceous, tertiary and jurassic systems, but also to the triassic, permian and pennsylvanian. This proves that the formation of nitre spots is not limited to the rocks of any given geological system. The analytical method used was as follows: — 100 gm. of finely-ground rock were placed in a large flask with 1000 cc. of distilled water and shaken in the shaking machine for 16 hours. The solution was then filtered through a CHAMBERLAIN-PASTEUR filter, and the nitric nitrogen determined by the aluminium reduction method (1).

Table II gives the results found for the different districts, characterised, consequently, by a high total content of soluble salts. With two exceptions, however, the nitrate content is not 1 % of the total content.

The nitrate is carried from the original rock by seepage water, and more rapidly where the water escapes from leaking irrigation canals which cut the shale strata at some high point, thus allowing the seepage water to follow the shale strata to the point of outcrop, where the evaporation of the water produces a nitre spot. In cultivated soils the accumulation of nitrates is only found where the conditions allow the free movement of seepage water. Nitre spots may reach such a degree of concentration as to make growth impossible, both in cultivated and in virgin soil. Their characteristics are: 1) a high nitrate content; 2) the presence of large quantities of other soluble salts (chlorides and sulphates); 3) brownish colour; 4) thin

(1) See *B*, 1914, No. 206. (Ed.)

crust over the surface ; 5) mealy or ash-like condition under the hard crust ; 6) beneath this material is the soil, made moist, ~~sticky~~ and glistening by the continual presence of calcium chloride, which is known to be very deliquescent.

In rocks, as in soils, the nitrates are not independent of other alkali salts, and no case is known where nitrates only have been found ; sulphates and chlorides especially occur in large quantities. The content of nitre spots in nitrate, as well as in other salts, is very variable.

The characteristic brown colour is not due to the nitrates, which are colourless, but to their solvent and decomposing action on the coloured organic compounds of the soil. The non-symbiotic bacteria are essential neither to the formation of the colour nor to that of the nitrates, their presence being purely incidental ; this is proved by the fact that nitrogen fixation by these bacteria is greater in dry-farm soils, where no nitre spots are found. Investigations have shown that the maximum fixation is 15.8 mg. of nitrogen (SACKETT) per 100 gm. of nitre spot soil, whereas, in dry-farm soil, this maximum is 51.8 mg. of nitrogen (GREAVES).

The authors reproduced nitre spots artificially in the laboratory : — 300 gm. of rich greenhouse soil were treated with an excess of sodium nitrate solution (10 %), and dried slowly in the sun. The dry soil had all the characteristics of the nitre spots, which it retained when treated with a saturated solution of mercuric chloride or a 5 % solution of carbolic acid, i.e. when the soil was sterilised, thus definitely eliminating the action of non-symbiotic bacteria.

130 — **Absorption and Other Modifications of Certain Fertilising or Anti-cryptogamic Compounds in Various Natural and Artificial Soils.** — DE WILKOSZEWSKI, BOGUMIL, *Archives des Sciences physiques et naturelles*, Vol. XLIV, No. 9, pp. 165-189; No. 10, pp. 256-275, 2 figs., 6 tables, bibliography of 23 publications. Geneva, 1917.

The author studied the absorption and other modifications undergone by ferrous and ferric sulphate; manganese sulphate, copper sulphate, calcium cyanamide, during their passage through natural and artificial soils, and through the physical constituents of the latter. The soils used were: — Loamy soils containing 0.38 % and 0.9 % of lime respectively.

"Angers soil", derived from the disintegration of schists, free from lime.

Loam freed from lime by repeated washing with hydrochloric acid.

Artificial soils and their constituents — Fontainebleau quartz sand, pure kaolin, pure calcium carbonate, heath soil composed entirely of humus without lime.

The soils, placed in glass dropping funnels 40 cm. high and 2 cm. in diameter, were gradually watered with solutions of the substances studied, and estimations were made of the liquid from the infiltration from time to time so as to keep count of the modifications which took place during the passage of the solutions through the soils.

The principal results may be summarised thus: —

**FERROUS AND FERRIC SULPHATES.** — The iron of the latter is more easily absorbed by the soil than the iron of the former, which, moreover, is found in the soil in the ferric state. This proves that ferrous iron is retained by the soil only after it has been oxidised, by hydrolysis, to ferric hydrate; it is even possible that the free acid acts partly on the hydrate formed and gives an insoluble basic salt which cannot be removed from the soil. This hydrolysis is greatly favoured by the presence of the soil particles. Calcareous soils retain the iron. Clay soils absorb ferric sulphate to a large extent, but ferrous sulphate only slightly, because oxidation takes place with difficulty.

**MANGANESE SULPHATE.** — After the solution has filtered through the soil it contains manganese oxides, perhaps even manganese peroxide; the catalytic action of manganese used as fertiliser is probably due to this phenomenon.

**COPPER SULPHATE.** — In the experiments with this salt the Cu<sup>++</sup> ion was retained in the form of a hydrate, or perhaps in the form of an insoluble basic salt, for the SO<sub>4</sub> ion is found in the filtration liquid.

In a general way it may be concluded that it is not the salts themselves which are retained by the soils, for they are hydrolysed, their base is rendered insoluble and the acid ion passes into the drainage water.

**CALCIUM CYANAMIDE.** — This is now known to change in the soil to urea, ammonium carbonate, nitrites and nitrates. The author further proved that when calcium cyanamide solution filters through the soil the change into urea and ammonium carbonate is much more marked than when solid cyanamide is dug in.

According to the author these changes are not due to bacterial action but to the capacity of the soil to facilitate the fixation of water, thus causing hydrolysis. This is proved by the fact that the transformation occurs immediately, both in arable and *sterilised* soil. Oxidation is favoured by soils of a spongy structure, such as infusorial soil, which has an obvious catalysing action, and where the nitrification of the cyanamide, urea and ammonium carbonate reaches its maximum. The production of nitrites was about 20 times greater in these soils than in ordinary ones.

Special attention should be given to the nitrification of the cyanamide in the soil in the absence of all organisms. The conditions under which this change takes place are not clear, and the author proposes to study them. During his studies he observed that Nessler's reagent does not form a red precipitate with the ammonium ion in the presence of calcium cyanamide.

131 - **Relation of the Transformation and Distribution of Soil Nitrogen to the Nutrition of Citrus Plants.** — See No. 173 of this Review.

132 - **Vegetation on Swamps and Marshes as an Indicator of the Quality of Peat Soil for Cultivation.** — DUNNEWALD, T. J., in the *Journal of the American Society of Agronomy*, Vol. IX, No. 7, pp. 322-324. Washington, October 22, 1917.

Most workers have concluded that the surface vegetation on peat gives no clue to the relative quality of the soil for the purposes of cultivation. On the other hand, farmers and drainage men often assert that peat on a black spruce (*Abies nigra*) or moss covered swamp is no good for cropping, whereas good black muck with elm or ash on it is the best kind of land to drain.

Under the drainage law of the State of Wisconsin, the author, a member of the staff of the Wisconsin Agricultural Experiment Station, examined an area of about 6 600 acres of scattered marshes and swamps. The upland is non-calcareous glacial drift, derived from granitic and sandstone rocks, with no limestone in the vicinity. The author wished to discover whether a favourable or unfavourable chemical condition would be found in different areas of the peat, and whether the vegetation would give any indication of such conditions.

A field study showed that spruce (*Abies nigra*) and tamarack (*Larix americana*) peat areas were the wettest, with the water table practically at the surface of the soil, and a covering of 12 to 18 inches of spongy moss. The depth of the peat or distance from the shore seemed to have little effect

on the kind of surface growth, and the degree of decomposition of the peat has hardly more effect.

Table I summarises the more important determinations made in the laboratory. All the samples, except No. 7, were taken from a depth of 6 to 20 feet. Samples 1 and 2 were taken from different parts of the same swamp. Fine sand grains were found in Nos. 7 and 10 and not included in the average loss on ignition. The data show that peat bearing black spruce and tamarack has 20 % less mineral matter, a much higher degree of acidity, and somewhat less nitrogen.

The greater acidity of spruce and tamarack peats may be due to the more continual flooded conditions of these swamps, and drainage experience shows that this acidity often disappears largely after the peat has been drained and cultivated. The author considers his experiments confirm the farmer's statement that trees, such as ash, elm, birch and white pine (*Pinus Strobus*) show a better quality peat than that on which grow only black spruce, tamarack, sphagnum moss, blueberries and cassandra (*Cassandra calyculata*).

Determinations of the solubility of the peats in 150 cc. of a 2 % caustic soda solution, showed acid peats to be from 3 to 8 % more soluble than the less acid ones, but, if an amount of the solvent sufficient to counteract the extra acidity of the spruce peats be used, the difference in solubility is not noticeable.

*Comparative determinations of the organic matter, acidity and nitrogen in peat soils in the same district bearing different classes of vegetation.*

Number of soil	Vegetation	Loss on ignition	True acidity	Total nitrogen
2	Tamarack ( <i>Larix americana</i> ) . . . . .	78.56 %	very strong	1.58 %

133 - **Practical Information for Beginners in Irrigation.** — FORTIER, SAMUEL, in U. S. Department of Agriculture, *Farmers' Bulletin* No. 864, pp. 38, 23 figs, 2 tables. Washington, September, 1917.

The U. S. Department of Agriculture has just published a revised edition of the *Farmers' Bulletin* No. 263, originally published on July 31st., 1906. It contains practical information for farmers who wish to settle in the centre and west of the United States where irrigation is essential. Besides general considerations on arid soils and water supplies for irrigation, the bulletin contains practical advice on selecting a farm under an irrigation system, and more detailed descriptions of the location and construction of farm ditches, the preparation of the land to be irrigated, the irrigation of a few of the staple crops (alfalfa, grain, potatoes, fruit trees and small fruits and vegetables), and the amount of water to be used.

Canal companies supply water to farmers by contract. Up to a few years ago the prevailing type of contract was one providing for the sale of a perpetual water right for a given tract of land, with an additional annual charge for the operation and maintenance of the canal system. This type is not usual now, the most common being the sale, with the land to be irrigated, of rights which carry an interest in the works supplying water, so that they become the property of the landowners when a fixed portion of the rights have been paid for. The cost of building the works is not included in the purchase price of the land, but is levied in the form of taxes.

The quantity of water to be supplied by the companies is fixed by contract. The most usual is a stream of given size, say 1 cubic foot per second for each 80 acres of land to be irrigated. Others agree to supply enough to cover the land to a given depth, say 2 feet, during each season.

Irrigation water may also be obtained from the Government at a stipulated price per acre. In this case the water is supplied to private landowners through a water users' association, in which all the landowners within the project become shareholders. The cost of a water right under a Government project varies from \$25 to \$29 per acre, and is payable in 20 annual instalments. When the payments for the water for the major portion of the land have been made, the operation and management of the irrigation system, exclusive of all storage reservoirs, passes to the owners of the land irrigated, to be maintained and operated at their expense.

After having discussed the construction of farm ditches, undertaken by the farmers themselves, the author gives the customary measurements of ditches, and, in a series of figures, gives the sections for specified ditches. The water is controlled by means of division boxes, made usually, and most economically, of wood. Stress is laid on the necessity of avoiding useless loss of water, either by faulty preparation of the soil, by carelessness, or lack of supervision in the distribution of the water. Experience shows that the great danger in irrigation, in all the arid districts of the United States, arises from the lack of efficient drainage of the soil. Where the natural drainage is insufficient, the salts from the sub-soil accumulate on the surface and soon make all cultivation impossible. It is, therefore, under such conditions, essential to have recourse to artificial drainage, which is almost as expensive to instal as a water supply.

134 - Irrigation of Semiarid Soils by means of Wind Engines, in U. S. A. — See No. 207 of this *Review*.

136 - The Value of Coconut Poonac as Manure. — BAMBER, M. K., in *Department of Agriculture, Ceylon, Leaflet No. 1*, p. 1, Ceylon, 1917.

MANURES  
AND MANURING

Owing to the difficulty of freight and consequent lower demand, the price of coconut poonac (native coprah cake) in Ceylon has fallen considerably, and the question of its use as a manure instead of a food has arisen. Analysis showed it to contain the following percentages of manurial elements: —

Nitrogen . . . . .	3.33 %
Phosphoric acid . . . . .	1.47
Potash . . . . .	1.29
Lime . . . . .	0.90
Soda (as salt) . . . . .	1.17

If coconut poonac is compared with other cakes now used as manure, it is seen that, for the same quantity of nitrogen: —

to 100 lbs. groundnut cake correspond 210 lbs. coconut poonac.	
» » » castor cake No. 1	150
» » » » No. 2	135
» » » rape cake	120

For this reason, in spite of its high food value, and considering that it is liable to become rancid on keeping unless very thoroughly dried, it is advisable, under present conditions, to use poonac as a manure in the country producing it.

137 - Saltpetre: Its Origin and Extraction in India. — HUTCHINSON, C. M. (Imperial Agricultural Bacteriologist), in *Agricultural Research Institute, Pusa, Bulletin No. 68*, 1916, pp. 24 + IV plates. Calcutta, 1917.

The author has made a new study of the saltpetre industry in India (1) and shows that, under favourable conditions, the prospects for an increased production of Indian saltpetre are very promising. The present sources are not fully worked on account of the primitive native methods and the low price of crude saltpetre. In view of the favourable soil and climatic conditions in Bihar, artificial nitre-beds would probably form a useful added source of saltpetre. The present methods do not allow all the nitrate present in the earth to be extracted.

It is, therefore, necessary to devise a new, practical method of extraction, and to see whether the efficiency of the method would depend upon a relaxation or revision of the restrictions imposed by the Salt Department. The present conditions of the saltpetre trade also demands examination to determine whether a greater demand would result from organised efforts to improve these conditions by eliminating the middleman and standardising the product itself.

138 - **Inventory of Seeds and Plants Imported by the Office of Foreign Seed and Plant Introduction During the Period from April 1 to June 30, 1914** (1).— U. S. Department of Agriculture, Bureau of Plant Industry, Inventory No 39, pp. 183 + X plates. Washington, 1917.

This inventory describes or lists 1019 recently imported plants, many of which were acquired *by exchange with official institutions or private experimenters*. Among the most important may be mentioned:—

**CEREALS.**— The two principal rice varieties of Tarragona, Spain (Nos. 37 696 and 37 697); a collection of South African wheats (Nos. 38 618 to 38 631), including the best Boer varieties adapted to the poor, unmanured lands of that district; 11 varieties of wheat (Nos. 38 343 to 38 353) have been developed by the wheat breeders of the Department of Agriculture of New South Wales and are considered worthy of trial in the south-west of the United States; a selected Danish 2-rowed barley ((No. 37 706) and a 6-rowed variety (No. 37 707), showing peculiar resistance to smut (*Ustilago Hordei* and *U. nuda*) and leaf-spot (*Septoria graminum*), and a good quality, yellow spring oat (No. 37 708), selected by the Royal Danish Agricultural Society of Copenhagen; the dwarf Black Grushevsk sorghum (No. 37 733) from the farm of the Grand Duke Nicholas in the Ekaterinoslav Province of Russia, which is distinguished by early maturity, even in very cold summers, and is the best yielder of 20 varieties tested there; a variety of maize (No. 38 544) grown by the Panetes Indians of the Upper Gy Parana (Machabo) River of Brazil.

**FORAGE CROPS.**— The most remarkable is *Merremia hederacea* (No. 38 647), a creeping plant of the convolvulus family from the Island of Guam; stock prefer it to any of the other forage plants of the island and it may be grazed all the year round; 59 wild or cultivated forage grasses from Brazil (Nos. 37 983 to 38 041); the Apitrefle, or bee clover (No. 37 937) from Prof. G. MARTINET of Lausanne, Switzerland, a variety of red clover with shortened, more open flowers, which enable the bees to collect the honey with greater ease; 2 annual species of clover from Budapest, *Trifolium angulatum* and *T. parviflorum* (Nos. 37 681 and 37 682), which remain dwarf in dry years, serving as pasturage, but grow high enough for hay in wet spots or in wet years; a wild type of Kentish white clover (*Trifolium repens*) (No. 38 579), which experiments at Armstrong College, Cockle Park, England, have shown to be superior to Dutch clover (2); many hardy varieties of sugar cane (Nos. 38 257 and 38 332), from Chengchow and Kaifeng, in Henan Province, which might be grown above the natural cane belt in the South of the United States and be useful for fodder, if not for syrup production; a very early-ripening Italian rye-grass (*Lolium multiflorum*) (No. 37 709), a meadow fescue (*Festuca elatior*) (No. 37 710), very resistant to rust (*Puccinia*) and an orchard-grass (*Dactylis glomerata* sub-variety "Olsgaard") (No. 37 711) all selected by the Royal Agricultural Society of Denmark; the Jua tree (*Ziziphus joazeiro*) (No. 37 923) from Joazeiro, Brazil, the fruit and leaves of which are used as food for stock.

(1) See R. Dec. 1917, No. 1129 (Ed.) — (2) See R. Sept. 1917, No. 814. (Ed.)

**FIBRE PLANTS.** — Caroa (*Neoglaziovia variegata*) from Joazeiro (No. 37 705), a wild Bromeliaceae growing on the São Francisco River, used by the native for ropes; the piassava palm (*Attalea funifera*) from Bahia (No. 37 868), from the fibre of which excellent brooms and brushes are made, while buttons are manufactured from the hard nuts.

**OIL-YIELDING PLANTS.** — Ngart (*Plukenetia conophora*) (No. 38 644), a creeping Euphorbiaceae, cultivated throughout the Ossidinge district (Cameroons). The thin-shelled nut contains a hard oily kernel. Experiments have shown that neither the kernel nor the oil contain harmful substances. The kernels, without the shells, weigh 4 or 5 grams and give 53.8 % of a drying oil, resembling linseed oil, and used by the natives. The fatty residue contains 45.6 % of protein.

The characteristics of ngart oil are: —

Specific weight at 17.5°C	—0.934
Congeaing point	— 33°C
Iodine number of the oil	177.3
Iodine number of the free fatty acids	187.4
Saponification number	192
Refractive index at 17.5° C.	—1.4830

(KRAUSE and DIESSELHORST, *Tropenpflanzer*, Vol. XIII, p. 282, 1909).

From the leaves of the carnauba wax palm (*Copernicia cerifera*) (No. 37 866), imported from Joazeiro, is obtained a wax that was formerly used for phonograph records. Its fruit is an excellent food for pigs, and it should not be impossible to plant groves of these palms for hog pasturage.

**GUM PLANTS.** — The true gum-arabic acacia (*Acacia vereh*) (No. 38 524), from Khartoum, may be capable of acclimatisation in the south-western desert district of the United States.

**DRINK-YIELDING PLANTS.** — Chici (*Salvia* sp.) (No. 38 048), from Zacuapam, Huatusco, Vera Cruz, Mexico; the seeds are put in water, where they swell and soften, mixed with sugar and red wine, and used as a drink; Ava or Kava (*Piper methysticum*) (No. 38 291), from Pago Pago, American Samoa, used as a drink.

**VEGETABLES.** — Many interesting species have been imported. A new variety of roselle (*Hibiscus sabdariffa*) (No. 37 698), called "Temprano", created at the Lamo Experiment Station, Philippine Islands, is a sport from the "Victor" variety, ripening 20 days earlier; it may be grown for jelly further north than the Victor can be grown; a cucumber (No. 37 700) introduced into the Philippines from Seharunpur, India, has shown resistance to insect attack and is proving one of the best varieties for cultivation in the tropics; a hybrid between thousand headed kale and kolh-rabi, obtained by E. WEBB and SONS, Wordsley, England; it has a thickened stem growing 5 feet high, which is suitable for forage during the winter; a Chinese ginger (*Zinziber officinale*) (No. 38 180) from Feichang, Shantung, the candied rhizomes of which are shipped in large quantities to the United States; 5 varieties (Nos. 38 356 to 38 360) of the very best starch, table and feeding potatoes of Polish origin, produced by M. HENRY DOROWSKI; the New Era potato, (No. 37 947), said not to be affected by potato blight (*Phytoph-*

*thora infestans*), has been obtained from New Zealand; a variety of the yam-pee yam (*Dioscorea alata*) (No. 37 943), produced at Avon Park, Fla., deserves serious study as it does well in very light sandy and rocky soil where potatoes will not grow; from Coban, Guatemala, have been imported seeds of the pacaya salad palm (*Chamaedorea* sp.) (Nos. 38 403 and 38 404) which, after 3 or 4 years, produces from 4 to 6 fleshy inflorescences about the size of ears of maize which, when cooked, make a delicate salad; it is believed that this species will grow in southern Florida.

FRUIT TREES. — Galo (*Anacolosia luzoniensis*) (No. 38 395), from the mountains of Cavite (Philippines) with a kernel having the flavour of maize; K'uei li tzu (No. 37 799) a superior large-fruited form of the blight-resistant Chinese chestnut (*Castanea mollissima*), introduced from Sianfu, Shansi; 24 new varieties of oriental persimmon (*Diospyros Kaki*), 11 of which come from Tongjapu (Nos. 37 648 to 37 658), including an especially valuable variety for drying purposes; an improved variety of *Diospyros lotus* (No. 37 811) used for stocks in the loess table-lands, which are very dry and alkaline; 5 new forms of persimmon from Shansi province (Nos. 37 661 to 37 665); the salt-bag persimmon and honey-pot persimmon (Nos. 37 672 and 37 678), the latter a prolific and showy bearer of fruit no larger than a cherry; both were imported from Shansi; 5 varieties from Shantung (Nos. 37 948 to 37 952), one of which is eaten pickled in brine; a staminate variety (No. 38 482), found in Bermuda, valuable as a polleniser. The importance of finding a pear resistant to blight (*Bacillus amylovorus*) induced MR. MEYER to continue his search for a better flavoured melting Chinese pear; from Shansi, Honan and Shantung he sent 15 varieties of more or less promise for breeding purposes (Nos. 38 240, to 38 242, 38 262 to 38 271, 38 277 and 38 278; the Rev. HUGH W. WHITE sent from Yencheng, Kiangsu, the Tangshan pear (No. 37 982), the only sweet, juicy pear with a woody taste he has seen; an apricot variety (No. 37 744) from the Dakhleh Oasis of Egypt, capable of resisting an annual temperature of 75° and monthly averages of 90° F.; from Shansi were received 14 varieties of Chinese jujube (*Ziziphus Jujuba*) (Nos. 38 243 to 38 247, 38 249 to 38 253 and 38 258 to 38 261), some with fruit as large, or larger, than hens' eggs, being more like small pears; they may be eaten fresh, cooked in various ways or preserved with honey, sugar, etc.; a variety of Chinese haw (*Crataegus pinnatifida*) (No. 38 176), the red-fleshed, large fruit of which will keep several months; the Fei peach (No. 38 178), considered the best in China on account of its size, lateness (middle of October), good shipping qualities and aromatic flavour; from Rio de Janeiro and Bahia, Brazil, came scions from 24 navel oranges, selected on account of their high yield, uniformity of fruit, sweetness, vigour, absence of spines and tendency to bear throughout the year; the Selecta orange (Nos. 37 796 and 37 840 to 37 842); the pear orange (Nos. 37 797 and 37 843); the bitter orange, laranja da terra (No. 37 775); the seedy sweet orange, laranja da china (No. 37 776); the last two are used as stocks for the navel orange; the lime orange (No. 37 784), with a flavour intermediate to that of the orange and the lime; a much esteemed orange-

ade is made from it (a typical fruit weighs 350 grams and gives 125 cc. of juice).

A Nakon Chaisri seedless Siamese pummelo (No. 37 724) from Bangkok; the alamoen from Surinam (No. 37 804), a superior variety of grapefruit; the desert kumquat (*Eremocitrus glauca*) (No. 37 712) and *Atalantia monophylla* (No. 38 511), from India and Ceylon; from Cavite province, *Euphoria cinerea* (No. 38 374), a remarkably sweet Sapindaceae; from Coban, 4 varieties (Nos. 38 478 to 38 481) of injerto (*Acradelpha viridis*); from Guatemala, the pitaya (*Cereus triangularis*) (No. 38 601), a pleasant flavoured, deep-purple fruit produced by an epiphytic *Cereus*; from Cuba, rare species of *Anacardium excelsium* (No. 38 209); from Rio de Janeiro the "fruta de condessa" (*Rollinia deliciosa*) (No. 38171); the guabiroba (*Campomanesia feniziana*) (No. 37 834), whose fruit is highly esteemed for jellies; "cambuhy da India" (*Eugenia campestris*) (No. 37 830), "cereja do Rio Grande" (*E. edulis*) (No. 37 831), *E. speciosa* (No. 37 832); *Rheedia brasiliensis* (No. 37 802) from Rio de Janeiro; from Januaria, the imbu (*Spondias tuberosa*) (Nos. 37 861 to 37 865), one of the most popular fruits of the interior of Brazil. To the collection of subtropical fruit have been added 24 choice varieties of hard-shelled avocados (*Persea americana*) (Nos. 38 477, 38 549 to 38 564, 38 578, 38 581, 38 583, 38 587 and 38 638 to 38 640) from the district of Coban, Antigua and the city of Guatemala, some at an altitude of 5000 feet; their fruit ripens late (winter and spring) and is of good quality.

139 - The Effect of Different Rotation Systems and of Fertilizers on the Protein Content of Oats. — THATCHER, R. W. and ARNY, A. C., in the *Journal of the American Society of Agronomy*, Vol. IX, No. 7, p. 344-348. Washington, D. C., October 22, 1917.

The experiments described were carried out at the Minnesota Agricultural Experiment Station.

Work on the influence of various fertilisers on the composition of oat grains has already been published (1), but it has rarely been carried out over more than one season, and the results are often inconclusive.

(1) WOODS, C. D. (Effects of Different Fertilizers upon the Composition of Oats and Straw, *Connecticut Storrs Agricultural Experiment Station Report* for 1892, pp. 47-56), found an apparent increase in protein content of both straw and grain in proportion to the quantity of nitrogen applied in the fertiliser.

WEISULL, M. (Cooperative Fertilizer Experiments in Malmöhus County, Sweden, 1902; Abstract in the *Experiment Station Record*, Vol. XV, p. 570, 1903), using the composition of the crop as an index for the fertiliser requirement of the soil, concluded that, since there was a slightly increased percentage of nitrogen in the grain and of potash in the straw from plots fertilised with these elements, and no consistent increase of phosphoric acid in grain from plots treated with phosphate fertilisers, the soils were in need of nitrogen and potassium, but not of phosphorus.

PINGREE, M. H. (The Influence of Nitrogenous, Phosphatic and Potassic Fertilisers upon the Percentage of Nitrogen and Mineral Constituents of the Oat Plant, *Pennsylvania Agricultural Experiment Station Report*, 1906, pp. 43-53), as a result of studies on oats in 1904, found that when nitrogen was applied alone there was a larger proportion of protein in the dry matter of the whole plant than when any other fertiliser was used. The proportion of protein was distinctly less on the unfertilised plot, still lower when potassium alone was used, and lowest of all when phosphoric acid was applied, even in a complete fertiliser.

In the studies described the samples analysed were taken from soil in which there was regular rotation, and, consequently, from different plots each season. The possibility of the effects being due to soil differences or to accumulations from previous soil treatments was thus reduced to a minimum. The same variety of oats was used in all the experiments; the rate and date of sowing, method of harvesting, etc., were identical each year. The methods of rotation and fertilisation were as follows:

**ROTATION PLOTS.** — *Continuous Oats.* — This plot was sown with oats each spring from 1909 onwards. Manure was applied at the rate of 6 tons per acre in the autumn of every third year; the last application was in 1915.

*Two-year rotation; oats and wheat or oats and maize.* — The method was the same as for continuous oats.

*Three-year rotation; no manure, maize, oats and clover. Model rotation.* — The same treatment as in the previous case, except that, for Model rotation, manure was applied the autumn before the planting of maize at the rate of 6 tons per acre.

*Four year rotation: maize, oats, wheat, clover.* — In the autumn preceding the maize, 8 tons per acre of manure were applied.

*Five-year rotation: maize, oats, wheat, clover, timothy hay.* — In the autumn preceding the maize, 10 tons per acre of manure were applied.

**FERTILISER PLOTS.** — On all these plots there was a three-year rotation of maize, oats and clover. The fertilisers were applied annually, each one separately. The phosphates and potash were applied at sowing time, the nitrate after the grain and maize were up. The kinds and quantities used were as follows:

*Commercial fertiliser only.* — When the seed bed was prepared 250 lbs. of acid phosphate and 100 lbs. of muriate of potash per acre were applied, half to the oats and half to the

TRETIKOW, S. S. F. (Influence of Mode of Cultivation on the Chemical Composition of Cereals; Abstract in *Experiment Station Record*, Vol. XXXIV, p. 230, 1916), found that barnyard manure increased the protein content of oats from 11.38 to 12.81 %.

LIPMAN, J. G. (The Associative Growth of Legumes and Non-legumes, *New Jersey Agricultural Experiment Station, Bulletin* 253, 1912), studied the effect of potassium sulphate and of sodium nitrate on oats grown alone and with peas, in large galvanised iron cylinders in the field and in pots in the greenhouse, and on other legume and non-legume combinations. He concluded that:

1) Under favourable conditions non-legumes associated with legumes may secure large amounts of nitrogen from them, even though this may not be shown by an increased proportion of nitrogen in the dry matter of the non-legume; 2) when sodium nitrate is applied to such crop mixtures, the non-legumes gain an advantage in the competition for moisture, light and plant-food, and the growth of the legume suffers. The legume contains not only less dry matter and nitrogen, but may also contain a smaller proportion of nitrogen in the dry matter.

LYON, T. L. and BIZZELL, J. A. (A Heretofore Annotated Benefit from the Growth of Legumes, *New York (Cornell) Agricultural Experiment Station, Bulletin* 294, 1911), noted an increased protein content in timothy when grown with alfalfa or clover, and of oats when grown with peas, as compared with that of the grass or cereal when grown alone on adjacent plots in the same season.

None of these studies deal with the effect of a legume in the rotation upon the protein content of the crops grown in the intervening years, and the work described in the paper under review seems to be the first on this subject.

maize. After the grain was up 300 lbs. per acre of nitrate of soda were applied, half to each crop

*Manure and commercial fertiliser.* — Manure at the rate of 6 tons per acre; commercial fertiliser as in the previous case.

*Manure and nitrate of soda.* — Each year 6 tons of manure per acre were applied to the maize, and, in addition, 320 lbs. per acre of nitrate of soda, half to the oats and half to the maize.

*Manure and muriate of potash.* — Each year 6 tons per acre of manure were applied to the maize, and, in addition, 200 lbs. of muriate of potash per acre, half to the oats and half to the maize.

*Manure and raw rock phosphate.* — Each year 6 tons of manure and 1 000 lbs. of raw rock phosphate per acre were applied to the maize.

*Manure and acid phosphate.* — Six tons of manure per acre were given to the maize, and, in addition, 400 lbs. of acid phosphate per acre, half to the oats and half to the maize.

Tables I and II, which give the results of the analyses of the oats from the various plots, show a definite effect of the rotation system on the chemical composition of the crop. Short rotations without clover or an intertilled crop requiring summer cultivation of the land, always gave oats with a low protein percentage. The three-year rotation with clover, with or without manure, and with at least one maize crop to provide summer cultivation, gave, without exception, oats of medium protein content. Longer rotations, with clover, or with clover and pasture; yielded oats of high protein content.

TABLE I. — *Effect of different rotation systems upon the protein content of oats, expressed as percentage of protein in the dry matter.*

Rotation	Manure per acre	Percentage of protein in dry matter			
		1914	1915	1916	Average
Continuous oats. . . . .	6 tons each 3rd. year. .	12.94	11.96	13.02	12.64
2 year, oats and wheat. .	do. . . . .	12.63	12.17	12.73	12.51
2 year, oats and maize. .	do. . . . .	13.25	11.95	13.13	12.78
3 year, oats, clover, maize	None (control)	14.00	14.66	15.46	14.71
3 year, oats, clover, maize	6 tons preceding maize .	14.63	13.45	14.92	14.33
4 year, wheat, clover, maize, oats . . . . .	8 tons " " . .	15.25	15.73	14.89	15.29
3 year, wheat, clover, pasture, maize, oats . .	10 tons " " . .	15.88	14.49	15.05	15.14

Table II shows a definite correlation between the protein content of the oat grain and the fertiliser treatment. Plots receiving nitrogenous fertilisers invariably produced grain with a higher protein content than plots receiving any other treatment. The single sample having the highest percentage of protein and the highest average for the four-year period was obtained with the use of nitrate of soda. The complete fertiliser contained enough readily available nitrogen to produce nearly the same effect upon the composition of the oats as the sodium nitrate alone. The potash fertiliser

produced oats with a slightly lower protein content than those from the control plots in every one of the four years. The phosphate fertilisers did not materially change the protein content of the grain, which was sometimes a little higher, sometimes a little lower, than that from the control plots. The average protein content was practically identical in the control, raw rock phosphate and acid phosphate plots.

TABLE II. — *Effect of different fertilisers upon the protein content of oats grown in a 3 year rotation of oats, clover, maize, expressed as percentages of protein in the dry matter.*

Fertiliser	Percentage of protein in dry matter				
	1913	1914	1915	1916	Average
None (control) . . . . .	14.56	14.63	13.09	14.92	14.30
Commercial only . . . . .	16.00	15.31	13.57	16.10	15.24
Manure + commercial . . . . .	—	14.69	15.00	15.57	15.09
Manure + nitrate of soda . . . . .	15.13	15.88	16.14	15.80	15.74
Manure + muriate of potash . . . . .	13.81	14.69	12.06	14.06	13.40
Manure + raw rock phosphate . . . . .	14.12	13.69	14.06	14.46	14.16
Manure + acid phosphate . . . . .	14.31	13.94	15.10	14.40	14.44

140 — **The Composition of Grain Sorghum Kernels.** — Le CLERC, J. A. and BAILEY, L. H., in the *Journal of the American Society of Agronomy*, Vol. IX, No. 1, pp. 1-16, bibliography of 7 publications. Washington, D. C., January, 1917.

This paper gives the average results of a large number of analyses of the seed of grain sorghums made at the Office of Cereal Investigations of the Bureau of Plant Industry, U. S. Department of Agriculture, during the 5 years 1908 to 1912, from crops grown at the Panhandle of Texas. The varieties analysed were durra, durra kafir, kafir, kaoliang, milo, broom-corn, shallu. From the data obtained interesting conclusions were drawn regarding: — 1) the correlation between the various chemical and morphological characters; 2) the influence of rain on the quantity and quality of the product.

A) CORRELATION OF CHARACTERS. — 1) Unlike wheat, there is no well-defined relation between the weight of 1000 grains of sorghum and the protein content (see Table I). In the milos alone there appears to be a slight tendency towards a positive correlation, *i. e.*, the heaviest grains are those richest in protein. In the other varieties the correlation is inclined to be negative.

2) Low protein content is usually accompanied with a high weight per bushel, and a low content in fibre, ash and pentosans.

3) There is often a correlation between large grains and a low fibre content; large grains have a relatively smaller superficial area than small grains, and consequently less bran, in which the greater part of the fibre is found. With this negative correlation with fibre goes also a negative correlation with ash.

4) There is a positive relation between the ash content and the protein and fibre content, but a negative relation between the ash content and the weight of 1000 grains and the weight per bushel.

B) INFLUENCE OF METEOROLOGICAL FACTORS. — The vegetative period, from April to ripening, was divided into three parts: — 1) April to emergence, 2) emergence to heading; 3) heading to ripening.

Table II summarises the averages of the data obtained. The rainfall of the second and third periods did not have any marked influence on the composition or yield; for example, milo, dwarf milo, brown kaoliang, black-hull kafir and red kafir had a high protein content in 1909 and a low protein content in 1908, although the rainfall during the second period was practically the same both years. The same results were obtained for the third period. Nevertheless there seems to be a certain relation between the harvest and the rainfall during the first period *i. e.* from April to emergence and also between the harvest and total rainfall.

The amount of protein per acre is higher when the rainfall is heavier. Thus, in 1908 and 1911, when there was a copious rainfall throughout the vegetative period and during the first period, the average protein yield per acre was from 181.4 to 245.4 lbs., whereas in 1909, 1910 and 1912, when the rainfall was less, the average protein yield varied between 66.8 and 110.3 lbs. per acre. The same relations observed for protein yield were also observed for grain yield.

TABLE I. — *Relation of protein content to the other constituents of sorghum.*

Variety	Protein N. $\times$ 6.25	Water	Ash	Fat	Fibre	Carbohy- drates	Weight of 1000 grains	Weight per bushel
	%	%	%	%	%	%	gram.	lbs
<i>Milo:</i>								
Protein less than 10.75 % . . . . .	10.69	9.36	1.59	3.27	1.43	73.69	34.9	58.2
Protein more than 13.70 % . . . . .	13.75	9.25	1.66	3.08	1.50	70.76	36.1	58.1
<i>Dwarf Milo:</i>								
Protein less than 9.62 % . . . . .	9.56	9.48	1.54	3.37	1.39	74.65	29.8	58.8
Protein more than 13.50 % . . . . .	13.56	9.57	1.67	3.23	1.53	70.48	32.1	57.7
<i>Brown Kaoliang:</i>								
Protein less than 11.50 % . . . . .	11.49	9.35	1.84	4.17	1.27	71.96	19.0	56.7
Protein more than 14.70 % . . . . .	14.75	9.88	1.95	4.07	1.50	67.94	17.7	55.2
<i>Blackhull Kafir:</i>								
Protein less than 12.60 % . . . . .	12.56	9.45	1.66	3.53	1.58	71.30	23.1	58.7

141 — **The Action of the Constituents of the Ash on the Life of Plants.** — EGOROV, M., in: I *Журналъ Опытной Агрономіи* (*Journal of Experimental Agriculture*), Vol. XVI, Pt. 4, pp. 270-280. Petrograd, 1915. — II. *Ibid.*, Vol. XVIII, Pt. 1, pp. 1-13 + 2 figs. 1917.

I. — The direct cause of the ripening of Gramineae, shown by the yellowing of the plant, is the migration of large quantities of magnesium to the seeds where it becomes fixed. In support of this hypothesis the author quotes the work of ARENDT and of WILLSTÄTTER (1), and describes his own experiments on oats, with and without castration, in which a chemical and morphological examination showed that, towards the period of ripening, castrated oats remain green. This is probably due to the fact that the magnesium does not leave the circle of the vital functions of the plant, so that there is no visible decrease in chlorophyll.

If later experiments confirm this hypothesis of the action of magnesium in the ripening of oats, it may be possible to solve the more important problem of why annual plants are only annual and not perennial.

II. — The action of the constituents of the ash on the life of plants is not sufficiently well known, and this second study is only an attempt to ascertain some specific properties of potassium. The experiment carried out by the author with young maize plants and a full-grown barley plant proves that, contrary to STOKLASA's thesis, the synthesis of the organic substance which takes place in the plant is not modified in ratio to the decrease of potassium oxide in the food. This modification is not sufficiently great to inhibit more or less the vegetative life of the plant (with regard to the amount of potash), but one function (perhaps even a series of functions) is essentially disturbed by a decrease of potash in the food; this function is the filling, or rather the emptying, of the grains of carbohydrates. In other words, the decrease of potash in the food results immediately in the transition of the carbohydrates from the organs in which their synthesis takes place to the parts where they accumulate temporarily. This fact accords with

(1) WILLSTÄTTER, Untersuchungen über Chlorophyll, 1913. — ARENDT, *Landwirtsch. Versuchs-Stationen.*, I, 1859. (Ed.)

the previous observations of M. ARENDT, according to which a small amount of potassium oxide remains in the grain, while the greater part, on the one hand, accumulates, after having fulfilled its functions, in other parts of the plant, and, on the other hand, passes into the soil or nutritive solution.

142 — **The Effect of Greenhouse Temperatures on the Growth of Cereals.** — HUTCHESON, T. B. and QUANTZ, K. E., in the *Journal of the American Society of Agronomy*, Vol. IX, No. 1, pp. 17-21, 1 fig., 2 plates. Washington, D. C., January, 1917.

The results are given of studies on the effect of different temperatures on the growth of wheat, oats, barley and rye from the date of sowing, December 21, 1915, till May 27, 1916, when the experiment was discontinued owing to the extreme heat in the houses. Four temperatures were chosen and kept constant, so far as possible, throughout the experiment: 75°F., 65°F., 62°F. and 58°F. The appended Table shows that the temperature has a considerable influence on the periods of heading, flowering and ripening of the different varieties. The order of maturity was sometimes almost reversed; thus at 75°F. oats headed first, at 58°F. rye was the first to head and oats came last. The Table also gives the number of tillers and heads for each plant and the average length of the culms and heads.

*Data on the growth of wheat, oats, barley and rye in greenhouses kept at various temperatures.*

58°	Dec. 31	Apr. 17	May 2	—	1.00	1.00	60.31	4.88

The most interesting results may be summarised as follows. —

1) A cool temperature produces earlier maturity, except in the case of oats; a high temperature stimulates a rank growth of tillers, thus wasting energy needed for the formation of the heads.

2) The cereal most susceptible to heat is barley, which produces a great number of tillers which do not head. Wheat and rye also suffer considerably, but less than barley. Oats suffer very little.

3) The grain yield is highest for the plants grown at cool temperatures, except in the case of oats, which shows no difference in this respect.

#### 143 — The Selection of Cereals in Sweden and the Increased Production thus Caused.

— NILSSON, N. HJALMAR (Lecture and report read before the Swedish Seed Society in 1917), *Sveriges Utsädesförenings Tidskrift*, Year XXVII, Pt. 4, pp. 172-203, 14 tables, 5 figs. Malmö, 1917.

Already before MENDEL's theory, taken up anew by DE VRIES, CORRENS, TSCHERMAK, had given a new impulse to the improvement of cultivated plants by selection and hybridisation, Prof. NILSSON EHLE, in his work on hybridisation at Svalöf, has admitted clearly the existence of hereditary units which are transmitted integrally and independently of each other, and from 1900 onwards, in his selection experiments by pure lines, he applied the methods and conceptions enunciated by JOHANNSEN.

It was from 1900 that the activity of the Experiment Station of Svalöf working on a modern scientific basis, and following a well-defined, practical aim, began to have a definite influence on the agricultural development of Sweden, with excellent effects, especially on the cultivation of cereals.

It is known that the productivity of a given plant varies from one locality to another, according to the special environmental conditions. Thus, a wheat giving a good yield in England may, on account of its slight resistance to cold, give very bad results in Sweden; such is the case of Square-head wheat. The selector, therefore, aims above all at uniting in one individual the characters *high intrinsic yield* and *resistance to the most unfavourable meteorological factor or phenomenon* in a given district. For this reason were established branch Stations, each with their own experimental fields, to complete and extend the activity of the main Station at Svalöf by forming centres of study in distinct districts differing from an agrogeological and meteorological point of view, such as Ultana, Lulea, Linköping (Westgöta), etc.

*Resistance to cold* is the most indispensable quality for every cereal in the south as well as in the north of Scandinavia. Moreover, certain districts in the east of Sweden have so little rain in spring that it is also necessary to introduce *drought resistant* varieties. Finally, in Svealand, the fertility of the soil causes such a rapid and rank growth of the culms that varieties *very resistant to lodging* are essential.

It has thus been possible to create, among the different varieties of cereals, various types, all of which are good producers and adapted to different and well-defined meteorological and agrogeological conditions. Thus Primus barley does well in cold, moist, heavy soils, whereas the varieties Gull and Hännchen prefer a dry climate and light soils; Guldregn oats,

which are the most widely cultivated, owe their popularity to their earliness and a capacity for adaptation almost equal to that of the native varieties, whereas Fyris oats are suited to clay soils, and the Klock variety, to peat or marsh soil rich in organic matter.

The author gives, in chronological order, the results obtained during the 25 years 1889-1915, in the selection of wheat (winter and spring), rye, barley and oats (white and black). Numerous tables (the most important of which are summarised here) give the details necessary to judge the work done; the yields in grain of the best varieties successively created and propagated by the Svalöf Station are all compared with the average yield of the native varieties, taken as 100.

WINTER WHEAT (1). — This must, above all, be resistant to low temperatures. This explains the reason why Squarehead, an excellent English wheat which has been used for the progressive improvement of the native varieties, but which, coming from less northerly districts, is more susceptible to cold, gave, in 1916, yields in grain inferior to those of native Swedish wheat (see Table I).

In 1890 the author, by individual selection, was able to isolate two lines, Grenadier and Extra Squarehead I, the first of which is distinguished by the quantity and quality of grain produced, as well as by the strength of its stems, the second by its resistance to cold and rust. By crossing these, so as to unite their qualities in one individual, he obtained Extra Squarehead II, which is superior to both the parents.

TABLE I. — *Relative indices of productivity of different varieties of winter wheat.*

Southern Sweden	Central Sweden (comparison with Svalöf)			
		Svalöf	Linköping	Utluna
Pansar . . . . . 140				
Fylgia . . . . . 135	0 826 Thule III . . . .	—	—	125.0
Sol II . . . . . 135	0 825 Thule II . . . .	128.5	121.1	113.6
Smaa . . . . . 131	0 823 . . . . .	113.4	111.7	108.8

Extra-Squarehead I . . 112				
Native Swedish wheat . 100				
English Squarehead . . 99				

In the relative indices of productivity a fairly good position is held by the Sol variety, derived by individual selection (pure line) from a Swedish variety. More resistant to cold and earlier than Extra Squarehead, it

is much in demand among the farmers of Götaland, where the rather late southern types are not adapted to the climate.

The cross Extra Squarehead II  $\times$  Sol I gave the hybrid Sol II, which holds almost the first place in the scale of relative indices of productivity and is to be recommended on account of its specific resistance to lodging.

From the native Swedish wheat by pure strains was obtained, in 1890, besides the Sol variety, the Kotte variety, also very resistant to cold and rust, but unsatisfactory on account of its bad quality grain and weak straw. By crossing it with Grenadier, M. EHLE (1) united in one type, called Pansar, the characters *productivity* and *resistance to lodging* of Grenadier, and the characters *resistance to cold* and *resistance to rust* of Kotte. Pansar wheat now gives yields which exceed by 40 % those of the native varieties. In 33 cultural tests in 1915 it gave in 7 cases more than 18  $\frac{1}{4}$  cwt. per acre, in 8 cases, less than 16 cwt. and in 18 cases between 16 and 18  $\frac{1}{4}$  cwt. per acre.

The cross Extra Squarehead II  $\times$  Småhvetet (early, productive Danish wheat) gave the hybrid Fylgia, which, in the north of Scania, has proved more productive and earlier even than Pansar.

To what extent is it possible to introduce into other districts of Sweden the varieties created at Svalöf? An answer to this question is found in Table I, which compares data obtained at Svalöf (southern Sweden) with those of Linköping and Ultuna (central Sweden); it shows that the varieties Renodlad Squarehead, Bore and Pudel, good at Svalöv, decrease rapidly in value as they go further north and, at Ultuna, are much inferior to native wheats. In 1904 M. EHLE crossed these (resistant to cold, ripening early) with the Pudel variety (productive, resistant to rust and lodging) and obtained successively the hybrids Thule I, Thule II and Thule III. The second, and the third even more, are excellent types for the north; at Ultuna, Thule III has a productivity index of 115, *i. e.* exceeding that of the native types by 25 %.

To sum up, at the present time Pansar and Fylgia combine, in good proportions, the characters *productivity* and *resistance to unfavourable meteorological phenomena*, but it has not yet been possible to unite in one type *all the valuable characters* of the parents to the exclusion of *all their defects*, so that new improvements still remain to be obtained, it is hoped, by the experiments now in progress.

SPRING WHEAT (2). — Spring wheat must both give a good yield and ripen early. This second condition is realised by the native wheats, but not the first. The selection of native wheats by pure strains, undertaken in 1890, gave the varieties Vårpår and Svalöfs Kolben. By crossing these with 0201 (a productive, but inferior quality type of Squarehead), two good hybrids were obtained which could be advantageously grown in Scania.

A different series of experiments is in progress for the southern districts. From among the descendants of the hybrid Kolben  $\times$  native Dalarne wheat,

(1) See R. March, 1916, No. 286. (Ed.) — (2) See R. Sept., 1917, No. 806. (Fd.)

was isolated a line which, while very early, produces on an average 8 % more than Kolben. By representing the productivity of Kolben by the index 100, the following indices are obtained for the other above mentioned varieties ; —

Vårparl . . . . .	107.5	Vårparl X 0201 . . . . .	110.9
0201 . . . . .	111.7	Kolben X 0201 . . . . .	112.9

RYE (1). — The point of departure for the selections was Östgöta Grårag (grey rye of Östergötland), and the last variety obtained is Stjärn, which yields 40 % more than the original native type. A valuable variety is Förädlade Wasa (obtained by individual selection from the Wasa variety), because its resistance to cold allows it to be grown in the Norrland, beyond the belt of the Stjärn variety.

TABLE II. — *Relative indices of productivity of the different varieties of rye.*

Varieties	Svalöf 1907-1915	Östergötland 1910-1915	Ultuna 1910-1915
Stjärn . . . . .	139.4	120.4	118.0
Petkuser . . . . .	130.2	110.6	112.1
Bretagner . . . . .	127.6	107.8	99.1
Förädlade Wasa . . . . .	122.9	109.1	107.1
Schlanstedter . . . . .	118.7	—	109.9
Midsommar . . . . .	112.8	—	—
Wasa . . . . .	103.9	—	99.8
Östgöta Grårag . . . . .	100.0	100.0	—
Native Ultuna rye . . . . .	—	—	100.0

Varieties of rye which gave excellent results at Svalöf and Östergötland did very poorly at Ultuna, but now selection and hybridisation experiments with native rye have been undertaken, and it is hoped to obtain varieties better suited to the northern latitudes.

TABLE III. — *Relative indices of productivity of the different varieties of barley.*

Varieties	Scania		Östergötland 1909-1916	Ultuna	
	Svalöf 1909-1916	Various localities 1908-1916		1897-1910	1900-1916

Flättring . . . . .	—	—	100.0	—	—

(1) See R. 1916, No. 287 (Ed.)

**BARLEY (1).** — For this cereal the results of selection are less obvious than for wheat and rye. It must, however, be noted: — 1) that, besides the yield, the quality of the grain for brewing must be largely considered, thus limiting the *quantitative* effects of selection; 2) that, at Svalöf, selection work was not begun with native types, but with the English barley Prentice, already improved, from which were obtained, by pure strains, the Princess variety, suited to light soils, and the Chevalier variety, suited to cold, heavy soils. Another variety, Hannchen, earlier and with strong straw, is one of the best, but is already surpassed by Gullkorn, a productive variety, resistant both to lodging and cryptogamic diseases.

**WHITE OATS.** — Selection was started with the Propsteier variety, already improved and productive, so that, like barley, the results do not, at the first glance, appear very remarkable. It is, however, sufficient to compare the last varieties obtained with the older, but still popular, native types, such as Ligowo II, Kubb, Förädlad Dala (selected Dala) to be convinced of their superior yield; thus, the new variety Kron produces 35 % more than Kubb. The variety Seger is also distinguished by the whiteness of its grain and Guldregn by the strength of its straw, the earliness and quality of its grain and its very thin glumes. The Svalöf oat varieties, unlike those of wheat and rye, also gave excellent results at Ultuna, as is seen from Table IV.

TABLE IV. — *Relative indices of productivity of the different varieties of oats.*

White oats			Black oats			
	Svalöf	Ultuna		Svalöf	Linköping	Ultuna
Kron . . . . .	106.3	102.7	Klock III . . .	121.3	114.4	101.8
Seger . . . . .	103.5	110.7	Stormogul . . .	120.7	111.8	99.9
Guldregn. . . .	102.5	107.9	Klock II . . . .	110.0	107.0	103.7
Propsteier . . .	100.0	100.0	Klock I . . . . .	109.5	—	—
Ligowo II . . . .	98.9	99.7	Fyris . . . . .	102.3	117.2	103.3
Förädlad Dala .	86.9	—	Tartarisk Plym .	—	75.5	88.7
Kubb . . . . .	78.4	—	Roslag . . . . .	100.0	100.0	100.0

**BLACK OATS (2).** — Selection was started with the varieties Roslag and Tartarisk Plym. From the former was obtained the variety Fyris (which holds first place at Linköping), from the latter, the varieties Klock I and Stormogul.

The cross Klock I × Guldregn (white) gave the hybrid Klock II. This, crossed in its turn with Stormogul, gave Klock III, which unites, in good proportion, the characters of the parents. The cross Klock II × Fyris has not yet given very definite results. Of importance are the attempts to cross the last varieties obtained at Svalöf with the native, northern types,

(1) See B. 1915, No. 369. (Ed.) — (2) See R. May, 1917, No. 122. (Ed.)

with the aim of uniting in one type the productivity and quality of the best varieties with the resistance to cold characteristic of the northern oats. The first result is the hybrid 01163 Dala  $\times$  Guldregn, superior to Dala in yield, resistant to cold, and earlier than Guldregn, which it could replace in the northern provinces. Very promising also are the hybrids Ligowo  $\times$  Nordfinsk = Björn, and Ligowo  $\times$  Nordland = Orion. All this hybridisation material has been sent for further study to the branch stations of Västernorrland, where the climatic conditions are more severe and difficult.

INCREASE IN THE PRODUCTION OF GRAIN DURING THE LAST 25 YEARS. — The new varieties created at Svalöf and distributed more or less widely towards the north, certainly produce much more than the native varieties, which they are gradually replacing entirely. This fact cannot fail to influence the production of grain, but there are no exact statistics which make it possible to determine to what extent the increased yield is due to the adoption of the new varieties, to the sowing of a larger area, or to the use of improved methods.

In the province of Malmöhus, the production of wheat which, during the five years 1889-1893, was 938 100 bushels, rose in 1909-1913, to 2 941 000 *i. e.* it was three times as great, and the largest increase was in 1899-1903, at the time when seed selected at Svalöf began to be used in extensive cultivation. Similar results were observed in the province of Kristianstad. With regard to increased production the districts of Sweden may be divided into three categories: —

- 1) Scania (provinces of Malmöhus and Kristianstad) . . . . . 200-300 %
- 2) Götaland and Värmland . . . . . 160 %
- 3) Svealand (provinces of Gotland, Dalarna and Gefleberg) . . . . . 25-30 %

In proportion as the north is approached the introduction of seed from Svalöf becomes more difficult and the results less certain, so that the increase in yield in the north is very limited.

It is interesting to determine in what proportions the three above-mentioned categories have contributed to the increase in production during the last 25 years. During the first five year period, 1889-1893, Svealand (3rd. category) holds the first place with 43.3 %, *i. e.* almost the half of the total production; then comes Scania with 34.5 %, and finally Götaland-Värmland with 23.2 %. During the last five year period, 1909-1913, the categories come in the following order: — Scania, 51.5 %; Svealand, 27 %; Götaland-Värmland, 21.5 %.

During the first five year period, 1889-1893, Sweden produced in all 3 717 671 imperial bushels of wheat; during the last, 1909-1913, it produced 7 494 838 bushels. In 1889-1893, 6 031 303 bushels of wheat were consumed, of which 50.6 % was supplied by the country and 49.4 % imported. In 1899-1903 the increased consumption was not compensated for by a proportionate increase in production, which does not represent more than 41.1 % of the total quantity consumed (8 998 073 bushels). Finally, in 1909-1913, in spite of the greater amount consumed (10 198 848 bushels), the wheat produced in Sweden rose again, and that imported fell to 46.4 % of the to-

tal consumption. By representing these fluctuations by relative indices the following figures are obtained : —

	1889-1893	1899-1903	1909-1913
Production . . . . .	1.01	1.2	2.0
Importation. . . . .	1.00	1.8	1.7

As is seen above, the effect of selecting superior types is first felt in the Scania district, where the climate is the same as that of Svalöf. The work of the branch stations, especially in Svealand, will allow the cultivation of wheat to be extended advantageously over large areas, where, at present, it cannot compete with barley and rye, and will help to decrease importation, seeing that the consumption curve tends to become horizontal. This rapid survey of the history of wheat in Sweden during the last 25 years, shows what results may be obtained, even in a short time, by the propagation of ultra-selected varieties.

For the other cereals—barley, oats and rye — it is more difficult to determine to what extent the varieties created at Svalöf have contributed to the increased production.

All the winter cereals, considered together, gave, in 1880, a yield in grain of 10.65 cwt. per acre, and in 1910, 13.38 cwt. The yield curve, which had remained more or less horizontal from 1885 to 1899, rose suddenly in 1909, just at the time when the seed from Svalöf began to be used in southern Sweden. As for the spring cereals, their yield per acre was 10.35 cwt. in 1880, 12.90 in 1910, and tended to increase, especially after 1905, that is to say, was in full keeping with the work of the main station at Svalöf.

Finally, to give an idea of the financial results obtained by the propagation of selected wheat, it is sufficient to mention the following facts: — in the province of Malmöhus alone, Pansar and Fylgia wheats, by increasing the yield by 7-8 %, gave a profit of about 1 million *crowns*, whereas Klock III oats, which yield 12 % more than Klock I, gave a profit of almost 4 million *crowns*, the cost of production remaining identical.

144 - **Linked Quantitative Characters in Wheat Crosses.** — FREEMAN, GEORGE F., in *The American Naturalist*, Vol. LI, No. 611, pp. 683-689, V tables. New York, November, 1917.

As the varieties of hard wheat and soft wheat used in the crosses described differ in having a number of visible characters exceeding that of the chromosomes (8) in the sexual cells, it was thought probable that a genetic linkage (1) of some of these might be found. The author

(1) Linkage was discovered in 1906 by BATESON and PUNNETT, who called it genetic coupling. By crossing the *Pisum sativum* varieties with purple flowers and long pollen grains with other varieties with red flowers and round pollen grains, it is seen that the 2 characters derived from each parent tend to be transmitted *coupled*, as if the respective determinants were found in one and the same chromosome. Cf. MORGAN, STURTEVANT, MULLER and BRIDGES, *The Mechanism of Mendelian Heredity*, pp. 48-77. London, Constable and Co., Ltd., 1915. — On this subject see R. January, 1918, No. 29. (*Ed.*)

undertook a study in order to determine if such a linkage exists between the texture of the grain (translucency or opaqueness) and the shape of the head determined by the ratio *width: thickness* (flattened heads and square heads).

One of the parents, No. 1, had hard, translucent grains and a flattened head; the other, No. 35, had soft, opaque grain and a nearly square head.

The hybrids of the  $F_1$  (1914) were intermediate to the two parents, both in the shape of the head and the texture of the grain (See Table I). In the  $F_2$  were found every possible degree of intergradation between the hard and soft grained variety. In order to facilitate the classification of the grains the author divides them into three groups: —

1st. Group: — Grains approximately resembling those of hard wheat. Hardness = 100.

2nd. Group: — Grains approximately resembling those of soft wheat. Hardness = 0.

3rd. Group: — All intermediate grains. Hardness = 50.

This classification allows the degree of hardness for each plant to be determined with facility. Thus, a plant having 60 % hard grains, 30 % intermediate grains, and 10 % soft grains, would be classified as follows:

$$(0.60 \times 1.00) + (0.30 \times 0.50) + (0.10 \times 0) = 0.75, \text{ or } 75 \%$$

Having classified the grains in this manner, the plants themselves may be divided into three groups.

	Percentage of hardness
1st. Group: — Hard wheats	over 66 $\frac{2}{3}$
2nd. Group: — Intermediate wheats	33 $\frac{1}{3}$ to 66 $\frac{2}{3}$
3rd. Group: — Soft wheats	less than 33 $\frac{1}{3}$

**CORRELATION BETWEEN THE TEXTURE OF THE GRAIN AND THE SHAPE OF THE HEAD.** — The flatter a head is, that is to say, the more its width exceeds its thickness, the higher will be the ratio or quotient obtained by dividing the first by the second. Is there any correlation between the degree of hardness of the grain and the value of this quotient? Table I gives, on this subject, data obtained in 1914 for the parents No. 1 and No. 35 and their  $F_1$  hybrids whereas Table II summarises the results concerning: 1) the parents and hybrids of  $F_2$  in 1915; 2) the parents and hybrids of  $F_3$  in 1916.

Tables I and II show there is a marked correlation between the texture of the grain and the shape of the head: the hardness of the first increases progressively in proportion as the ratio *width: thickness* increases in the second. Are we here concerned with a true genetic correlation, or a simple physiological correlation due to the fact that long, thin, hard grains, poor in starch, thus less capable of filling the glumes than are soft, well plumped grains, rich in starch, tend to form a flattened head? This problem may be solved in various ways: —

1) In the pure line of hard wheat No. 1 are always found soft grains, the number and proportion of which vary with the individual. Those plants producing a *smaller* proportion of soft grains have not more flattened heads

TABLE I. — Data concerning the two parents and their hybrids of  $F_1$  (1914)

	Value of ratio width : thickness															Total number of plants	Average value of ratio of width thickness	Character of grain
	Number of plants.																	
	0.60 to	0.70 to	0.80 to	0.90 to	1.00 to	1.10 to	1.20 to	1.30 to	1.40 to	1.50 to	1.60 to	1.70 to	1.80 to	1.90 to	2.00 to

Hybrid No. 1 × No. 35 . . . . .	—	—	—	—	1	1	5	4	9	12	3	4	—	—		39	1.56	Intermediate
Soft wheat No. 35 . . . . .	1	4	3	1	2	1	—	—	—	—	—	—	—	—		12	0.88	Soft

TABLE II. — Data concerning the two parents and their hybrids of  $F_2$  (1915) and  $F_3$  (1916)

	1915			1916			Character of grain
	Total number of plants	Average value of ratio of width thickness	Character of grain	Total number of plants	Average value of ratio of width thickness	Character of grain	
Hard wheat No. 1 . . . . .	298	1.57	Hard	253	1.45	Hard	Hard
Hard wheat No. 1 . . . . .	352	1.55	Intermediate	55	1.50	Intermediate	Intermediate
Hybrid No. 1 × No. 35 . . . . .	693	1.55	Hard	2 275	1.59	Hard	Hard
Hybrid No. 1 × No. 35 . . . . .	1 226	1.29	Intermediate	1 291	1.33	Intermediate	Intermediate
Hybrid No. 1 × No. 35 . . . . .	332	1.11	Soft	963	1.24	Soft	Soft
Soft wheat No. 35 . . . . .	166	0.95	Soft	241	1.04	Soft	Soft

than those producing a *larger* proportion of soft grains, as would be the case in physiological correlation.

2) There are varieties of hard wheat with square heads, and varieties of soft wheats, such as Little Club, with rather strongly flattened heads.

3) Plants which have an abnormal correlation between texture of the grain and the shape of the head transmit it to their descendants, as is shown by the figures for 1915 and 1916 given in Table III. In this case physiological correlation can play no part, whereas the phenomenon could easily be explained by genetic correlation, by the theory of exchange of elements between chromosomes as expressed by MORGAN's "cross over" theory (1). In any case, it cannot be a question of physiological correlation.

TABLE III. — *Inheritance of non-conformity to usual correlation between the shape of the head and the texture of the grain.*

Number	Parents (1915)		Descendants (1916)	
	Ratio <i>width: thickness</i>	Per cent hardness	Ratio <i>width: thickness</i>	Per cent hardness
132	0.93	98	1.34	88
169	1.10	50	1.24	73
210	1.20	50	1.35	93
232	1.25	100	1.33	86
239	1.33	60	1.30	88
263	1.00	64	1.17	61
279	1.27	50	1.35	79

It may be objected that, if there were a constant genetic link between the characters "shape of head" and "texture of grain", the linkage should be complete, whereas, on the contrary, there is considerable regression. This objection may be met by the observation that, apart from the fact that these characters are *quantitative*, and, therefore, subject to fluctuation round a mean, it may be admitted that the genetic factor for the texture is linked only with *one* of the factors determining the shape of the head. This would result in the partial correlation found.

CONCLUSION. — The data presented seem to show that the two characters, "hardness of grain" and "high ratio *width: thickness*" derived from the hard wheat parent No. 1, tend to come out together in the segregates of the  $F_2$  and  $F_3$  generations, *i. e.*, that there is genetic linkage between one or more of the factors (genes) controlling the grain texture and head shape in the two varieties employed as parents.

145 — Selection of "Kanred" a New Wheat Variety, in Kansas, U. S. A. — See No. 159 of this Review.

146 - Studies on the Contamination of the Pollen of Rye with the Help of "Indicator Plants" in Sweden. — HERIBERT-NILSSON, N. (Seed Selection Station of Weibullsholm, near Landskrona, Sweden), in *Zeitschrift für Pflanzenzuchtung*, Vol. V, Pt. 2, pp. 89-114, fig. 7-16, V tables. Berlin, 1917.

In his experiments on the selection of rye at the above mentioned station, the author uses a method differing in many respects from that usually followed; instead of sowing the descendants of the selected plants side by side, he scatters them in fields of wheat or fodder Gramineae in order to prevent their crossing.

In such work it is necessary to determine the manner and proportion in which the pollen of a plant, or group of plants, when carried by the wind, may reach the flowers of other plants, even if they be at a considerable distance. This may be done in three ways: —

- 1) The determination of the percentage of flowers setting in plants almost completely self-sterile, cultivated apart.
- 2) Direct collection of the pollen.
- 3) The use of "indicator plants" ("indicators").

1) PERCENTAGE OF FLOWERS SETTING. — In normal rye plants this is, on an average, 5 %. Higher averages, exceeding 10 %, may be attributed to contamination by other plants, or groups of plants. According to the author's observations, plants separated from each other by a distance of about 30 metres may be considered as practically isolated. Isolated plants at the same distance not of one plant, but of a group of plants (covering an area of about 0.5 square metres), are exposed to contamination at the rate of 10 %, bringing the percentage setting up to 15 %.

2) DIRECT COLLECTION OF THE POLLEN. — This is done by means of glass slides covered with liquid paraffin, placed at various distances from the rye-plot in the direction of the prevailing wind.

3) THE USE OF "INDICATORS". — In 1913, during work on the selection of the Danish variety of rye, Brattingsborg, the author noticed a plant distinguished, even when fairly ripe, by the persistence of chlorophyll in the stem, leaves and glumes, thus having the appearance of a wild grass. The green parts of the plant, then, *do not ripen* (1).

Hybridisation experiments with the normal type showed this "non-ripening" character to be recessive, the  $F_2$  individuals being distributed as follows: 296 normal to 96 green (theoretically, 294 to 98), according to the Mendelian ratio 3 : 1. As this green type is very rare (less than 1 in a million) and recessive, it is particularly well adapted for use as an "indicator" very sensitive to contamination. By studying the descendants of a given individual of this type it is possible to determine exactly the seeds arising from self-fertilisation and those arising from cross-fertilisation (contamination): the former will produce "green" plants, whereas the latter, fertilised by the normal dominant type, will produce normal individuals exclusively. It is, therefore, impossible to find a more exact instrument for measuring contamination.

(1) On the ripening of cereals see No. 141 of this Review. (Ed.).

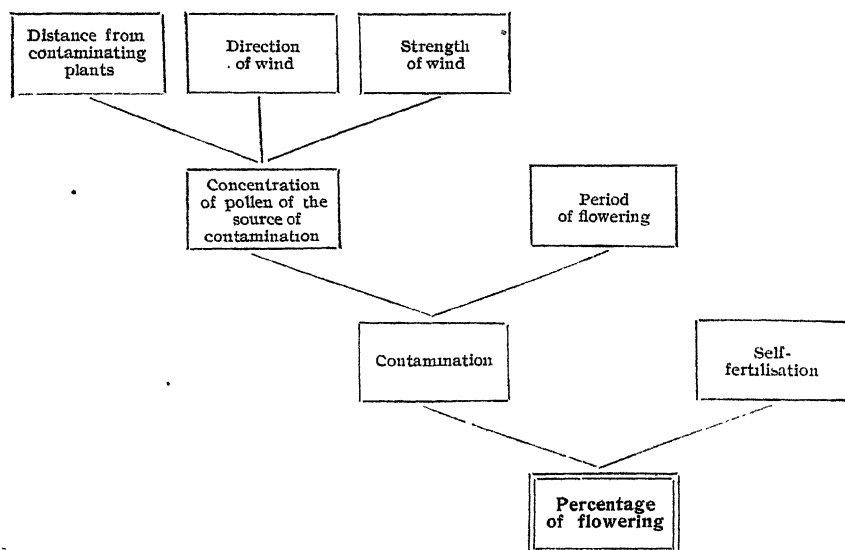

By applying this method it was found that 10 % of the isolated rye plants, at a distance of 50 metres from plots (rye) measuring 1 to 2 square metres, are subject to contamination. The larger the plots, the greater is the danger of contamination, as is shown by the following figures with regard to a rye plot measuring 3 500 square metres :

Distance between isolated plants and plot	Percentage of contamination
50 metres . . . . .	51.4 %
250   "   . . . . .	46.3
350   "   . . . . .	29.7
400   "   . . . . .	19.0

The use of "indicators" allows the effect of contamination on a whole crop to be studied. This is impossible by the usual methods owing to the impossibility of distinguishing between normal plants from self-fertilised seeds and normal plants from cross-fertilised seeds. It was thus possible to determine that the effect of contamination by the 3 500 square metre plot on a group of 20 "indicators" 60 metres away, was 37.3 % *i. e.*  $\frac{1}{3}$  rd. less than the effect on isolated plants. This difference is explained by the fact that the pollen of 20 plants in a group has a marked protective action.

The fertilisation of a group of plants exposed to contamination is obviously dependent on the state of the pollen mixture which spreads over the plot. The mass of pollen coming from a given group of plants becomes less dense in proportion as the distance it travels from its origin, or "source of contamination" is greater, in other words, its "concentration" is proportionately less strong. In a group A of plants exposed to contamination by another group B, the percentage of flowering depends both on the concentration of the pollen produced by the group A itself, and that of the pollen of group B, whereas the fertilisation of isolated plants depends almost solely on the concentration of the pollen of the "source of contamination", for their pollen concentration is almost equal to nil.

Other experiments have, moreover, shown that plants of the same group, or isolated plants situated at equal distances from the "source of contamination" may present widely differing percentages of contamination. Thus, for the 20 plants mentioned above figures were found varying between 9.6 and 68 %. These differences in one group may be explained as follows : The plants do not all flower at the same time ; in proportion as the absolute number of plants increases (and, consequently, the area of the plot), the total period of flowering increases and the amount of pollen spread over the neighbouring plants, or groups of plants, becomes thicker. The late-flowering plants exposed to contamination will, therefore, show a higher percentage of contamination than the early-flowering ones. The percentage of flowers setting of an almost self-sterile plant exposed to contamination is, therefore, dependent on many variable factors which may be represented by the following figure : —

The use of "indicators" also made it possible to show that the muslin bags placed over inflorescences to prevent access by foreign pollen do not have the desired effect. Rye pollen granules measure  $0.05 \times 0.06$  mm., and easily pass through the openings of this muslin, which have a diameter of 0.15 to 0.20 mm. Four "indicator" plants isolated by means of muslin gave descendants divided up as follows :

Indicators				Descendants			
Number of plants	Number of flowers	Number of seeds	Percentage of flowering	Number of plants	Contaminated plants (ripening normally)	"Indicator" plants (green)	Percentage of contamination
1045	74	59	79.6	28	14	14	50
1046	112	53	25.0	28	27	1	96.4
1047	50	15	30.0	6	4	2	67.7
1048	74	14	18.9	5	5	—	100

Of the descendants of the "indicator" 1045, half were produced by self-fertilisation, the other half by contamination. It is, therefore, a plant possessing a high degree of self-fertilisation, which shows that the pollen from the rye fields penetrates the muslin so abundantly that it may advantageously compete with the pollen of a self-fertile plant. In the other three cases the percentage setting is lower, an average of 25 %, and the average contamination is 83.3 %. Consequently, the majority of the plants (more than  $\frac{4}{5}$  ths.) are fertilised by foreign pollen which penetrates the protective hood, thus proving the inefficiency of muslin for isolation purposes.

147 - **Inheritance of Endosperm Colour in Maize.** — WHITE, ORLAND E., in the *American Journal of Botany*, Vol. IV, No 7, pp. 396-406, 4 tables, bibliography of 11 publications. Lancaster, Pa., July, 1917.

The factors determining the endosperm colour in maize have been studied by many authors (CORRENS, LOCK, HAYES, EMERSON, BURTT-DAVY, etc.). The author crossed varieties with yellow endosperm, California Golden Pop ( $Z_{14}$ ), with a Hopi variety and *Zea Caragua* ( $Z_{21}$ ), both with white endosperms. The results he obtained led him to form conclusions in part widely different from those of preceding authors who admitted the existence of two determinants of the yellow.

In the cross California Golden Pop ( $Z_{14}$ )  $\times$  *Zea Caragua* ( $Z_{21}$ ), the  $F_1$  hybrids had uniformly white endosperms, or, at the most, in certain cases, slightly yellowish ones. The cross California Golden Pop  $\times$  Hopi gave similar results.

Of 9 663 grains of the  $F_2$  generation of California Golden Pop ( $Z_{14}$ )  $\times$  *Zea Caragua* ( $Z_{21}$ ), 6 999 were white and 2 664 were yellow. Assuming the difference between these two varieties to be due to one single factor (monohybridism), the theoretical numbers would be 7 248 white and 2 416 yellow grains, in accordance with the Mendelian ratio 3 : 1. There is, therefore, a satisfactory agreement between the actual and theoretical values.

With regard to the yellow colour it should be noted : 1) it was lacking in uniformity, all shades from a dark yellow to a very light lemon yellow being present on the same ear ; 2) in some ears the yellow was principally confined to the base of the grain, nearest the point of attachment.

By crossing the hybrids  $Z_{14} \times Z_{21}$  of the  $F_1$  generation with the parent  $Z_{21}$  (*Zea Caragua*), white grains only were obtained.

In the  $F_1$  generation, of 6 208 grains, 4 703 were white and 1 505 yellow ; according to the Mendelian ratio 3 : 1, the figures should have been 4 656 white and 1 552 yellow. In this case the white, as well as the yellow grains, showed little uniformity in colour ; this is largely due to the segregation of factors affecting the texture and degree of translucency and opaqueness.

In all the experiments described above the inflorescences were always isolated by muslin or parchment bags (2 leaves). By leaving  $Z_{14}$  in contact with varieties with orange colour grain, fully exposed to cross fertilisation, ears with a large number of orange grains were obtained. From this it may be inferred that the orange grain variety is dominant to the yellow  $Z_{14}$  (California Golden Pop) variety. Under similar conditions,  $Z_{21}$  (*Zea Caragua*) always produced exclusively white grains.

Taking these data as a basis, the author explains the colour differences between  $Z_{14}$  and  $Z_{21}$  by the presence or absence of a single inhibitory factor, A, which prevents the development of the yellow colour, even in presence of the factor Y, which determines the yellow pigment. In the absence of this factor the grains may be either yellow or white. Four combinations are possible.

1) AAYY	white endosperm
2) AAyy	white       "
3) aaYY	yellow     "
4) aayy	white       "

By crossing these combinations with each other, the following colours would be obtained for the endosperm of  $F_1$  and  $F_2$ :

Cross	$F_1$	$F_2$
1 (white) $\times$ 2 (white)	white (AAYy)	all white
1 (white) $\times$ 3 (yellow)	white (AaYY)	3 white; 1 yellow
1 (white) $\times$ 4 (white)	white (AaYy)	13 white: 3 yellow
2 (white) $\times$ 3 (yellow)	white (AaYy)	13 white: 3 yellow
2 (white) $\times$ 4 (white)	white (AaYY)	all white
3 (yellow) $\times$ 4 (white)	yellow (aaYy)	3 yellow: 1 white.

The formula of the California Golden Pop ( $Z_{14}$ ) variety would be aaYY, that of the *Zea Caragua* ( $Z_{21}$ ) variety AAYY. All the common varieties with white endosperm would have the formula aayy, i. e., would possess neither the determining factor Y, nor the inhibitory factor A. These formulae would explain all the phenomena and combinations observed during the author's experiments.

148 - The Relation of Cob to Other Ear Characters in Maize. — GRANTHAM, A. E., in *Journal of the American Society of Agronomy*, Vol. IX, No. 5, pp. 201-217, 13 tables + 2 figs, bibliography of 4 publications. Washington, May, 1917.

This paper gives the results of a series of studies on the relation of the characters of the cob (size, weight, density) to those of the grain (depth, thickness, weight, yield), made at the Delaware Agricultural Experiment Station from 1910 to 1915. For the work were used 3 500 ears of maize of the Johnson County White variety, cylindrical in shape, with straight rows of kernels. Only the upper part of the ear deprived of the tips, so as to leave a cylindrical section 12 cm. long, was used. The following characters were studied:

- 1) Weight of section.
- 2) Number of rows.
- 3) Circumference of ear.
- 4) Thickness of kernel: determined by counting the number of kernels in 10 cm.: minimum number, 18; maximum, 32; average, 24.827  $\pm$  0.0229.
- 5) Weight of shelled grain or yield in grain: minimum 105 gm.; maximum, 285 gm.; average, 196.321  $\pm$  0.2639.
- 6) Weight of cob: minimum 15 gm.; maximum, 75 gm.; average, 36.500  $\pm$  0.083.
- 7) Circumference of cob: minimum, 7 cm.; maximum, 15 cm.; average, 10.571  $\pm$  0.011.
- 8) Depth of kernel: determined by the difference in the diameters of the cob and ear: minimum, 0.7 cm.; maximum, 1.9 cm.; average, 1.248  $\pm$  0.0015.
- 9) Weight of individual kernel, determined by counting the number required to weigh 10 gm.: minimum number, 18; maximum, 52; average, 27.805  $\pm$  0.0513.
- 10) Density of cob; determined by dividing its weight by its circumference; minimum, 0.12; maximum, 0.54; average, 0.328  $\pm$  0.0006.

The appended table give the coefficients of correlation between the various characters of the cob and those of the kernels, calculated by DAVENPORT's formula (1).

*Coefficients of correlation between the characters of the cob and those of the kernel.*

Characters		Coefficients of correlation
7) Circumference of cob and	5) Weight of grain per section. . .	0.4118 $\pm$ 0.0095
	6) Weight of kernel. . . . .	-0.0185 $\pm$ 0.0114
	8) Depth of kernel. . . . .	-0.1789 $\pm$ 0.0110
	4) Thickness of kernel. . . . .	-0.1053 $\pm$ 0.0113
9) Weight of cob and . . .	5) Weight of grain per section. . .	0.3064 $\pm$ 0.0103
	9) Weight of kernel. . . . .	-0.1837 $\pm$ 0.0110
	8) Depth of kernel. . . . .	-0.0747 $\pm$ 0.0113
	4) Thickness of kernel. . . . .	-0.1500 $\pm$ 0.0111
10) Density of cob and . .	5) Weight of grain per section. . .	-0.0728 $\pm$ 0.0113
	9) Weight of kernel. . . . .	-0.1959 $\pm$ 0.0111
	8) Depth of kernel. . . . .	-0.0039 $\pm$ 0.0113
	4) Thickness of kernel. . . . .	-0.0513 $\pm$ 0.0114

CONCLUSIONS. — 1) The *yield of grain* per ear increases with the circumference of the cob; the correlation between these characters is fairly high.

2) There is also a high correlation between the *yield of grain* and the *weight of the cob*.

3) The *depth of the kernel* increases with the *density of the cob*, but the correlation is slight.

In these three cases, contrary to the following ones, there is positive correlation.

4) An increase in the *density of the cob* tends to decrease the *weight of kernel*; the negative correlation is moderate.

5) There is a moderate degree of correlation between the following pairs of characters: *circumference of cob* and *depth of kernel*; *weight of cob* and *average weight of kernel*; *weight of cob* and *thickness of kernel*.

$$(1) \text{ DAVENPORT's formula is: } r = \frac{\sum D_L D_W}{\sigma_L \sigma_W}$$

where  $D_L$  represents the difference between the lengths and average length  
 $L_W$  " " " " the weights and average weight  
 $\sigma_L$  " " standard deviation of the length  
 $\sigma_W$  " " " " of the weight.

The maximum degree of *positive* correlation is expressed by the coefficient + 1; the maximum degree of *negative* correlation by the coefficient - 1; the absence of any correlation is represented by 0. Thus, the value 0.9 shows a very high positive correlation, whereas the value 0.1 shows a very low correlation. (Ed.)

6) There is slighter negative correlation between the *circumference of the cob* and *thickness of kernel*.

7) There is a low negative correlation between the pairs of characters: *weight of cob* and *depth of kernel*; *density of cob* and *yield of grain*.

8) The negative correlation between *density of cob* and *depth of kernel* is very slight.

9) There is practically no correlation between the *circumference of the cob* and the *weight of the individual kernel*.

There are, then, in certain cases, clear and well-defined relationships between the characters of the cob and those of the kernels, so that measurements of the cob might be a valuable aid in the selection of maize.

149 - On Abnormal Ears of Maize Obtained from Seeds Treated with Copper. — JUNGELSON, A., in *Revue Générale de Botanique*, Vol. XXIX, No. 344-345, pp 241-248 + 261-285 + 1 fig. + plates 17-21. Paris, 1917.

The experiments described were carried out in 1914 and 1915 to determine the effect of copper salts on the growth of cereals, and of maize in particular.

The 1914 experiments showed that treating maize seed with copper salts had the following effects: —

1) The germinating power of the seeds is weakened.

2) The poisoning of the seedlings is often shown by the appearance of a bluish streak on the leaves.

3) The growth of the plants is slower and flowering is, consequently, retarded.

4) Poisoning of the seeds may give the plants issued from them special capacities, tendencies to vary, shown by the appearance of abnormal ears, which, by their own characters, and by those of the grain they contain, are removed from the racial type.

5) These new characters are faulty and retrogressive, and the injurious effects increase with the increased poisoning of the seed — greater length of time of poisoning, closer contact of the poison and albumen as a result of previous mutilation.

The 1915 experiments gave the following complementary conclusions: —

6) Different copper salts have the same effect.

7) The facility of the plants to give abnormal ears varies with the concentration of the copper solution in which the seed has been placed.

8) Copper has no well-defined effects, and seeds treated in an identical manner give birth to different anomalies.

9) The tendency to vary of a plant from poisoned seed may be shown by qualitative or quantitative effects, by the appearance of multiple anomalies, or of more uniform ones in greater number.

10) The new characters of the seed and the grain are not stable, and do not seem to reappear in the descendants.

11) The tendency to vary of the parent-plant is fixed in the seed which produces irregular and retrogressive ears.

PRACTICAL RESULTS. — A) The copper treatment, used in agriculture to protect seeds against cryptogamic diseases, may have an accessory and in-

jurious influence. The specific characters of the varieties cultivated may, under this influence, disappear and be modified in an undesirable sense. The deterioration of local varieties of cereals, of which farmers have so frequently complained during recent years, may be partly due to this anti-cryptogamic treatment, and may prove a serious obstacle to the improvement and selection of the desired characters. It is even possible that chemical poisoning may produce deeper and more lasting results than those obtained in the author's experiments, and that poisoning or development in a medium which is not the customary one may be the cause of diverging types or of deformities.

B) By the action of peculiar and graduated chemical influences easily adapted to experiment, it may be possible to throw some light on the natural factors of evolution, and perhaps also on the mechanism of racial variation. It is of no account if pathogenic actions are concerned, for it is still unknown whether they may not be direct or indirect causes of the variation and evolution of plant species or forms.

150 - **Correlations between the Chemical and Morphological Characters of Sorghum.** — See No. 140 of this Review.

151 - **An Interesting Bud Variation in the Duchess Apple.** — DORSEY, M. J., in *The Journal of Heredity*, Vol. VIII, No. 12, pp. 565-567, fig. 9. Washington, December, 1917.

WILLIAM BARDWELL found in his orchard near Excelsior, Minn., a Duchess apple which differs from the others of the same variety in its deeper red colour and harder skin.

Typical Duchess apples are pale yellow, more or less covered with irregular dark red streaks overlying lighter irregular blotches. The sport has the same yellow background, but is covered with a solid, dark red colour on exposed parts, shading, at the apex, into a lighter red overlaid with darker streaks. The skin, being harder, is more resistant during cooking. It is probably a case of bud variation which, since it shows the same productiveness and quality as the parent plant, might be successfully propagated by grafting, and form a new type of great market value owing to its fine colour.

It was in this manner that Collamer and Hitchings arose from Twenty Ounce, and that Banks arose from Gravenstein, all being forms characterised by a deeper colour. Banks is usually called Red Gravenstein, and, similarly the new Duchess type might be called Red Duchess.

152 - **A Bottle Necked Lemon.** — SWINGLE, LEONHARDT, in *The Journal of Heredity*, Vol. VIII, No. 12, pp. 559-560, 1 fig. Washington, December, 1917.

Bud sports are much more frequent in the citrus family than is supposed, and are of importance in the improvement and standardisation of varieties.

In a Eureka orchard near Corona, Cal., the author observed a limb sport which had grown till it comprised a large part of the tree. It was distinguished by its bottle-necked fruit and narrow, sharply pointed leaves, resembling those of the willow or peach.

A search led to the discovery of several other identical cases. There

is no transition between the normal part of the tree and the sporting branch. The apparent correlation which is always found between the bottle-necked fruit and the narrow pointed leaves, is of interest.

The fruit of these branches is of inferior quality and market value. This shows the necessity of careful pruning and the rejection, for grafting purposes, of buds or scions showing such variations to however slight a degree.

153 - Cereal Cultural Experiments made in 1916 at the Agricultural Station of Flahult, Sweden. — VON FEILITZEN, HJALMAR, in *Svenska Mosskulturforenings Tidskrift*, Year XXXI, No. 6, pp. 465-469. Jönköping, 1917.

1) SPRING RYE AND WHEAT, BARLEY AND OATS. — In yield of grain oats hold the first place, followed by barley, rye and wheat.

	Variety	Beginning of earing	Duration of growing period, days	Grain Yield	
				Cwt. per acre	Compared with that of oats = 100
Oats. . . . .	Sege	July 25	138	21.16	100
Barley . . . .	Korn	July 15	119	19.70	93
Rye . . . . .	Primus	June 25	131	15.80	75
Wheat . . . .	Jätte	July 20	138	16.20	77

As in the previous year Gulkorn barley gave a yield much superior to that of Primus; taking that of Primus as 100, the values 140, 167, 114 are obtained for the years 1914, 1915, 1916, respectively.

2) COMPARATIVE EXPERIMENTS WITH DIFFERENT VARIETIES OF OATS. — The Kron variety holds the first place with a yield of 21.13 cwt. of grain per acre; next comes Probsteier with 20.08 cwt. The two new Svalöf hybrids, Orion and Björn, specially designed for the northern districts, gave, in 1916, a yield slightly higher than that of Tysk Mosshafre (a German oat for peaty soils).

	Straw per acre Cwt.	Grain per acre Cwt.	Weight per quarter lbs.	Weight of 1000 grains gms.	Per cent- age of grain	Number of days from sowing to appearance of inflores- cences	Duration of growing period days
<i>White Wheats:</i>							
Kron . . . . .	43.51	21.22	303.1	34.5	73.7	93	146
Probsteier . . . . .	43.60	20.08	296.0	34.6	73.6	92	146
<i>Black Wheats:</i>							
Tysk Mosshafre . .	37.87	18.97	311.4	30.5	73.1	62	129
Orion . . . . .	41.76	19.42	324.2	34.5	73.0	84	130
Björn . . . . .	41.95	19.38	324.8	30.1	74.2	86	130

155 - **The Colour Classification of Wheat.** — HAYES, H. K., BAILEY, C. H., ARNY, A. C. and OLSON, P. J. (Committee of the Minnesota Section of the American Society of Agronomy), in the *Journal of the American Society of Agronomy*, Vol. IX, No. 6, pp. 281-284. Washington, D. C., September, 1917,

The colour of wheat is due to the joint effect of two factors: — 1) The presence or absence of a brownish-red or orange-yellow pigment in the bran layer; 2) the physical condition of the endosperm cells. These latter may be corneous or starchy, according to the density of the cell contents or the relative amount of space occupied by air cavities or vacuoles. The confusion which has arisen with regard to the colour classification of wheat is probably due to the use of a single term to describe the combined visual effect of these two characters.

The presence or absence of a red pigment in the bran layer is of little importance in indicating milling value; but the density of the endosperm is of great importance. Pigmentation is definitely inherited and appears under widely varying environmental conditions. Although somewhat modified by climatic conditions, the intensity of pigmentation is a varietal character. With the same degree of pigmentation, a starch kernel has a lighter appearance than a corneous kernel, but there is no difficulty in distinguishing a starchy pigmented kernel from a starchy white kernel.

If inheritance be regarded as a characteristic manner of reacting to a certain environment, it may be said that the physical condition, whether corneous or starchy, is an inherited character. This, however, does not apply to the density of the endosperm, which is very dependent upon environmental conditions, a fact which must be borne in mind in classification in view of its relation to milling qualities.

The authors, therefore, propose the following classification: —

Two columns are necessary: 1) *Pigmentation*; 2) *Physical condition or density*.

Under *pigmentation* it is proposed to use the term "red" to show the presence of a brownish-red pigment in the bran layer. This is to be modified by the term "light" when the degree of pigmentation is less than is usual in red wheats. Although the pigment may not be entirely absent from the bran layer of the so-called "white wheats", it is so nearly so that the term "white" is proposed in classifying them. It is recognised that a corneous kernel with a non-pigmented bran layer will not appear perfectly white. The colour of the bran layer is not affected by the density of the endosperm, although the visual appearance due to the two factors is influenced by the relative endosperm density.

Under *physical condition or density* are proposed 4 terms to denote the various gradations of endosperm density: 1) corneous; 2) sub-corneous; 3) sub-starchy; 4) starchy.

In the first group, *corneous*, would be included only the uniformly corneous sample.

The second group, *sub-corneous*, would include samples whose kernels approach either of the following conditions or a combination of both: —

a) samples containing  $\frac{2}{3}$  corneous kernels and  $\frac{1}{3}$  starchy or sub-starchy kernels; b) samples in which nearly all the kernels approach the corneous group, the greater part having only a small percentage of starchy endosperm.

The third group, *sub-starchy*, would consist of kernels  $\frac{2}{3}$  of which are starchy and  $\frac{1}{3}$  corneous, or kernels which contain a small amount of corneous matter with the larger part of the endosperm starchy or a combination of these two conditions.

The fourth group would be limited to uniformly starchy material.

It is recognised that samples intermediate to two of these groups will often be found; in such a case they must be placed in the group they most closely resemble; the signs + and - may be used to show they are slightly above or below the average of the group in which they are placed.

**156 - The Effect of Sodium Nitrate Applied at Different Stages of Growth on the Yield, Composition and Quality of Wheat.** — DAVIDSON, J. and LE CLERC, J. A. (Plant Chemical Laboratory of the Bureau of Chemistry, U. S. Department of Agriculture), in the *Journal of the American Society of Agronomy*, Vol. IX, No. 4, pp. 145-154. Washington, D. C., April, 1917.

LE CLERC and LEAVITT (1) have shown that the variation in nitrogen content of wheat is independent of the original nitrogen content of the seed used. This conclusion is confirmed by other work which has proved that the soil is a minor factor in this variation, so that it appears that the principal factor, within the limits of these experiments, is climate. It remains to be found which factor, or combination of factors, of climate (rainfall, sunshine, altitude, temperature) are the principal causes of such variation, and whether climate affects the metabolism of the plant directly, or indirectly by modifying the amount of plant food in the soil.

The work described in this paper was undertaken to study this question. It was thought that climate might be the cause of the variation of available nitrates at different stages of growth and it therefore seemed advisable to study the effect of the application of sodium nitrate at these different stages. The experimental plots measured 1 square rod each, and the nitrate was applied, either in solution or in the solid state, at the rate of 320 lbs. per acre in 1, 2 and 3 lots at the following periods: — 1) when the crop was about 2 inches high; 2) at heading; 3) milk stage.

The results show, above all, that the addition of sodium nitrate at the early stages of growth stimulates the vegetative growth and, consequently, increases the yield. Though the presence of sodium nitrate at the time of heading gives a better quality grain as regards colour and protein content, it does not affect the vegetative growth. At the milk stage, sodium nitrate has no effect on the yield, quality or protein content of the grain. The same results were obtained whether the nitrate was applied in solution or in the solid state; except during the first stage, when the use of nitrate in

(1) LE CLERC, J. A. and LEAVITT, S., Trilocal Experiments on the Influence of Environment on the Composition of Wheat, in U. S. Dept. of Agr., Bureau of Chemistry, Bull. 128, pp. 18. 1920. (Author).

solution gave higher yields, probably on account of the better distribution of the fertiliser in this form.

The experiments also confirmed the negative correlation between the nitrogen content and yellow colour of the grain; potassium chloride alone appears to increase this colour, but does not effect either the vegetative growth or the chemical composition of the grain.

**157 - Experiments with Wheats at Verrières, Seine-et-Oise, France.** — De VILMORIN JACQUES, in *Comptes Rendus des Séances de l'Académie d'Agriculture de France*, Vol. II No 38, pp. 1077-1085. Paris, December 5, 1917.

In this paper are given the results of experiments with wheats begun in 1917 at Verrières by M. PHILIPPE DE VILMORIN, and continued after his death by the author.

**F. — SPRING WHEATS.** — The following seven varieties were studied in 1917: *Aurore*, *White Fife*, *Manitoba*, *Red Fife*, *Kolben*, *Mars rouge sans barbes*, *Marquis*.

The *Manitoba* wheat used for comparison was from the old VILMORIN stock, received from the Corbeil mills in 1900, and grown ever since at Verrières.

The experiments were divided into two parts:

1) *Aurore*, *Manitoba*, *Red Fife*, *Marquis* and *Kolben* were compared. These wheats were classified as follows: —

Earliness	Yield
1st. — <i>Aurore</i>	1st. — <i>Aurore</i> with 46.20 lbs* per 120 sq. yds.
2nd. — <i>Marquis</i>	2nd. — <i>Kolben</i> » 31.46 » » » » »
3rd. — <i>Manitoba</i>	3rd. — <i>Marquis</i> » 30.25 » » » » »
4th. — <i>Kolben</i>	4th. — <i>Manitoba</i> » 23.98 » » » » »

In the 1917 yield tests *Kolben* took a good place, much higher than that it had held previously.

2) The number of days elapsing between the date of sowing and that of harvesting were:

Sown on March 1.	Sown on March 15
<i>Aurore</i> . . . . . 148 days	<i>Marquis</i> (received and sown on the 20th. only) . . . . . 136 days
<i>Mars rouge sans barbes</i> . . . . . 156 »	<i>Aurore</i> . . . . . 138 »
<i>Manitoba</i> . . . . . 159 »	<i>Mars rouge sans barbes</i> . . . . . 144 »
<i>Red Fife</i> . . . . . 162 »	<i>Manitoba</i> . . . . . 147 »
<i>White Fife</i> . . . . . 162 »	<i>White Fife</i> . . . . . 147 »
<i>Kolben</i> . . . . . 169 »	<i>Red Fife</i> . . . . . 151 »
	<i>Kolben</i> . . . . . 153 »
Sown on April 1.	Sown on April 15.
<i>Aurore</i> . . . . . 129 days	<i>Aurore</i> . . . . . 114 days
<i>Marquis</i> . . . . . 131 »	<i>Marquis</i> . . . . . 114 »
<i>Mars rouge sans barbes</i> . . . . . 135 »	<i>Mars rouge sans barbes</i> . . . . . 116 »
<i>Manitoba</i> . . . . . 138 »	<i>Manitoba</i> . . . . . 116 »
<i>Kolben</i> . . . . . 138 »	<i>White Fife</i> . . . . . 116 »
<i>Red Fife</i> . . . . . 114 »	<i>Red Fife</i> . . . . . 120 »
<i>White Fife</i> . . . . . 144 »	<i>Kolben</i> . . . . . 120 »

*Aurore* wheat leads in every respect, being very closely followed by *Marquis* wheat.

*Aurore* wheat. — This wheat is of Australian origin, a hybrid of the *Jacinthe* and *Ladoga* varieties obtained in Australia. It was imported in 1892 in the *VILMORIN* collection. One plot of *Aurore*, sown on May 1st., was harvested on July 31st., after exactly 3 months, with a yield of 1177 lbs. for 25 ares (17 cwt. per acre), in medium soil, with average cultural methods. Sown during the first days of March, *Aurore* gave, in 1916, a fine yield of over 26 cwt. per acre. In 1917, however, though sown, under bad conditions, it only gave a yield of 17 ½ cwt. per acre. *Aurore* wheat is an excellent spring wheat for France.

*Marquis* wheat. — This variety, obtained in Canada by DR. CH. SAUNDERS, is rapidly taking the place of all other varieties in that country. Its earliness, surpassed by no other wheat in America, and which, in the experiments in question, is very near that of *Aurore*, gives it a great value. The advantage it has in being a selected wheat, and not mixed, like *Manitoba* is very appreciable. It would be useful to grow it in France on account of its earliness and yield.

*Mars Rouge sans barbes* comes after *Marquis*, followed immediately by the series *Fife*, alias *Manitoba*.

II. — RESISTANCE TO COLD OF THE DIFFERENT VARIETIES OF WHEAT. — Observations on this point were made in the annual experiment on winter yields at Verrières. In this district the frosts continued almost without interruption from January 20th. to February 15th., sometimes reaching — 16° C.

### *Classification in 1917 according to resistance to cold.*

#### 1. Varieties resisting well or hardly suffering.

- 1) *Rouge d'Atterch* (completely immune)
- 2) *Tererson* (resisted well, none lost)
- 3) *Dattel* (id.).
- 4) *Automne rouge barbu* (id.).
- 5) *Nouette de Lausanne* (id.).
- 6) *Épautre blanc sans barbe* (id.).
- 7) *Perle du Nuiscement* (a few plants only lost).

- 13) *Briquet jaune* (id.).
- 14) *Lamed* (id.).
- 15) *Rouge d'Ecosse* (id.).
- 16) *Brownick* (id.).

#### 2. Varieties suffering but little.

- 17) *Grosse Tête* (barely 1/5 lost)
- 18) *Massy* (id.).
- 19) *Tererson à épi blanc* (id.).
- 20) *Chiddam d'Automne à épi rouge* (id.).
- 21) *Little Joss* (id.).
- 22) *Trésor* (1/4 lost).
- 23) *Blanc à paille raide* (id.).
- 24) *Blé Hybride No. 115* (lost 1/3).
- 25) *Blé Hybride No. 104* (id.).
- 26) *Blé Manitoba* (from Goldschidt, 1/3 lost).
- 27) *Mars de Suède rouge barbu* (1/3 lost)
- 28) *Géant du Milanais* (id.).

3. *Varieties suffering.*

- 29) Roseau ( $\frac{1}{2}$  lost).
- 30) Bordeaux (id.).
- 31) Bon Fermier (id.).
- 32) Japhet (id.).
- 33) Champlan (id.).
- 33-a) Blé Hybride No. 119 (id.).
- 34) Blé Hybride No. 120 (id.).
- 35) Hatif Inversable (id.).
- 36) Blé Hybride No. 134 (id.).
- 37) Blé Hybride No. 105 (id.).

4. *Varieties suffering badly.*

- 38) Noé ( $\frac{2}{3}$  frost bitten).
- 39) Bordier ( $\frac{3}{4}$  frost bitten).
- 40) Alliés (id.).
- 41) Blé Hybride No. 118 (id.).
- 41-a) Saumur d'automne (id.).
- 42) Rouge de Saint-Laud (id.).
- 43) Rieti (id.).
- 44) Odessa sans barbes (id.).
- 45) Engrain commun (id.).
- 46) Barbu a gros grain ( $\frac{7}{10}$  frost bitten)
- 47) Cazeaux ( $\frac{4}{9}$  frost bitten).

5. *Varieties completely or almost completely frost bitten.*

- 48) Rouge prolifique barbu (suffered very badly).
- 49) Chiddam blanc de Mars (id.).
- 50) Pithiviers (almost entirely frost bitten).
- 51) Touzelle rouge de Provence (id.).
- 52) Hérisson sans barbes (id.).
- 53) Mars rouge sans barbes (id.).
- 54) Richelle blanche de Naples (a few plants only remained).
- 55) Gironde (id.).
- 56) Blé Hybride de printemps No. 187 (id.).
- 57) Pétauielle blanche (id.).
- 58) Six-rowed Poulard (id.).
- 59) Poulard d'Australie (id.).
- 60) Richelle blanche hâtive (id.).
- 61) Saumur de Mars (completely frost bitten.).
- 62) Blé Hybride de printemps No. 192 (id.).
- 63) Blé Hybride de printemps No. 193 (id.).
- 64) Aurore (id.).
- 65) Mars barbu ordinaire (id.).
- 66) Mars rouge barbu (id.).
- 67) Pétauielle noire de Nice (id.).
- 68) Amidonnier blanc barbu (id.).
- 69) Amidonnier blanc amélioré (Alvargonzalez) (id.).
- 70) Miracle (id.).
- 71) Belotourka (id.).
- 72) Médéah (id.).
- 73) Pologne (id.).

The following results were obtained in experiments on "successive autumn sowing", in which various hybrids were studied and many known varieties were used for comparison.

. *Chi! am winter wheat (white ears).*

Sown on October 20 (almost entirely frozen).  
Sown on December 1 (resisted well).

*Blé des Alliés.*

Sown on October 20 (almost entirely frost bitten).  
Sown on December 1 (resisted well).

*Blé Aurore.*

Sown on October 20 (entirely frost bitten, except 3 plants).  
Sown on December 1 (very badly attacked).

This last observation was made only out of curiosity and is of no practical value as spring wheats are never sown in autumn.

158 - **Wheat Growing in Tuscany:** — FERRARI P, in *L'Italia Agricola*, Year **LIV**, No. 11, pp. 385-389. Piacenza, November 15, 1917.

In Tuscany, the production of wheat, as such, has relatively little importance, for the topographical conditions of the province are more suitable for the cultivation of woody plants (vine, olive, etc.), so much so

that, in many localities, the total production of the farm does not suffice for the consumption of the farm family. On the other hand, Tuscany produces seed of one of the best wheat varieties ("gentil rosso") which, when cultivated in the fertile plains of upper Italy, has considerably increased the unit production of this cereal.

Tuscany was the first region of Italy to improve the local varieties of wheat by careful selection, a process that has been practised since 1890.

Tuscan wheats are all soft varieties: —

"Gentil rosso": — most widely grown wheat in Tuscany; awnless; long, blond grain, tillers abundantly.

"Gentil bianco": — when mature, ear and grain are lighter coloured than those of the previous variety; awnless; seed not so long as that of "gentil rosso"; good cropper, especially in hill regions (650 to 1300 ft.).

"Calbigia": — ear coloured like that of "gentil bianco"; grain reddish, this is why, in several localities, the name "calbigia" is used as a synonym of "gentile", and local varieties are often called "calbigia bianca" or "calbigia rossa", according to the colour of the grain.

"Mazzocchio": — round ear, with long, stiff awns; does not tiller so well as the preceding varieties, and is best suited to hill regions; is less affected by shading by the olive and other trees, and is little liable to lodging; full, reddish grain, giving a good yield of flour that makes excellent bread.

Among other local varieties are: "grano rosso" (red wheat) and the bearded "cascola", chiefly grown in the provinces of Pisa and Grosseto; "civitella" with a long, white, bearded ear; "andriolo", bearded, suitable for hill regions. All these varieties are of secondary importance compared with "gentil rosso", which may be considered as the typical wheat of the greater part of Tuscany.

Amongst introduced varieties, *Rieti wheat* is grown in level regions where the crop is liable to rust. Some trials have been made of the *hybride inversable de Vilmorin* (Vilmorin's non-lodging hybrid) wheat in flat districts where the shade produced by trees is harmful.

On the author's suggestion the "R. Accademia dei Georgofili" of Florence opened, in 1890, a competition for bonuses for the selection of wheat seed, in order to improve local varieties. Owing to the good results of this competition, another was organised in 1895, always limited to local varieties. These competitions showed up the value of the "gentil rosso" and "gentil bianco" varieties, especially of the former. Many competitors showed that, by methodic seed selection, were obtained uniform seed characters, greater tillering power, a longer ear, a greater number of fertile spikelets, and, in consequence a greater unit yield. This is why many farmers of the Val d'Arno (province of Florence), among those who had won prizes at the competition, commenced the large scale production of "gentil rosso" for seed. In 1905, the Florentine "Consorzio agrario" commenced the sale in Tuscany and upper Italy, where "gentil rosso" was very successful. Afterwards, many farms sold "gentil rosso" seed wheat directly to the "Consorzi agrari" of Venetia, Lombardy and Emilia, the repre-

sentatives of which visited the crops before the harvest to ascertain their uniformity. Then the "Istituto per le sementi" was founded to deal particularly with the provision of and preparatory work for seed wheat, the diffusion of which was greatly helped by the "Federazione italiana dei Consorzi agrari".

In 1913 it was calculated that, in 18 provinces of Piedmont, Lombardy, Venetia and Emilia, the wheat "gentil rosso" was grown on 86 050 acres or 35 % of the total area under wheat (see *Il frumento in Italia*, Ministero di Agricoltura, Industria e Commercio, Ufficio di Statistica Agraria, pp. 33. Rome, 1914).

Allowing that the locally produced seed can be used for 5 years, about 70 000 quintals of the original wheat seed must be imported every year.

The example given by the "R. Accademia dei Georgofili" of Florence has been followed by the Bologna Agricultural Society, the R. Academy of Agriculture of Turin, the Treviso Agricultural Association, the Agricultural Committees of Catania and Pisa, the "Cattedra Ambulante di Agricoltura" of Piacenza, etc.

159 - "Kanred", a New Wheat for Kansas. — JARDINE, W. M., in the *Journal of the American Society of Agronomy*, Vol. IX, No. 6, pp. 257-266. Washington, D. C., September, 1917

ORIGIN. — The new wheat, called Kanred, is the product of a single head selected in 1906 from Crimean (No. 1435 of the Office of Cereal Investigations, U. S. Department of Agriculture) by the Department of Botany of the Kansas State Agricultural College. In the autumn of 1906, 554 selected heads were sown, and 451 were harvested in the following season. These and 79 other selections were sown in single rows alternating with Kharkof wheat for purposes of comparison. In 1908, 533 selections were harvested, 122 of which were chosen for increase. In the autumn 10 rows of each of these were sown with alternate rows of Kharkof. In 1909, 89 selections were harvested, sown in rows as before, and, in 1910 the harvest, together with 100 other strains, was passed over to the Agronomy Department for further trial. From 1911 to 1916 several of the most promising selections, including Kanred, were grown in pots. From 1914 onwards Kanred was grown at the sub-station at Hays, Kansas, and in co-operative tests with farmers throughout the hard winter-wheat belt. Since 1915 it has been grown at the sub-stations at Colby and Garden City, Kansas. Milling and baking tests and chemical analyses of the most promising strains have been made each year since 1912.

CHARACTERISTICS. — Hard winter-wheat, bearded, with whitish, glabrous glumes and reddish grain of the well-known Crimean or Turkey type. In habit of growth and general appearance the plant and grain cannot be distinguished from Turkey and Kharkof unless it be in minute botanical differences which have not been determined. It usually heads and ripens somewhat earlier than Turkey and Kharkof, but this difference is not sufficiently constant for identification.

*Average yields and other Agronomic Data of Kanred,  
Turkey and Kharkof Wheats at Manhattan, Kansas from 1911 to 1916.*

Variety	Yield in bushels per acre	Date of heading	Date of ripening	Weight in lbs. per bushel
Kanred . . . . .	31.1	May 21.8	June 19	59.2
Turkey . . . . .	26.5	May 22.8	June 20.8	59.5
Kharkof . . . . .	25.9	May 23.1	June 21.2	58.3

In the tests carried out at the three above-mentioned sub-stations or in cooperation with farmers, Kanred always surpassed, in unit yields, the varieties compared with it, ripened before or at the same time as the other wheats, and appeared to bear the winter better.

*Average Results of Milling and Baking Tests made at Manhattan  
from 1912 to 1915.*

160 - **Maize in Madagascar.** — REYNIER, F., in *Revue Agricole et Vétérinaire de Madagascar et Dépendances*, Year II, No. 13, pp. 9-16. Tananarive, November, 1917.

Maize does very well at all altitudes in the island of Madagascar, where it is cultivated throughout the year. In certain dry districts, if the necessary water is supplied by irrigation, maize may be had in all its stages — a sight often seen in the well-irrigated valleys of the south-west. It is, however, chiefly grown along the western coast from November, when it is sown after the first rains, till March, when it is harvested. Two, or even three, harvests are possible all over the island, one being without irrigation. The province of Tuléar alone could produce 50,000 metric tons of grain exclusive of the amount necessary for local consumption.

Before the war it was not possible to grow maize for export in Madagascar, owing to the cost of transport to the large European ports, freight being quite prohibitive. As a result of the war, the production of maize has decreased in the belligerent countries and increased in those neutral countries which could grow it more largely; as the demand is in excess of the supply, there is scope for newcomers on the market. These facts, together with the increased prices and levelling of freight on all shipping lines, completely change the position of Madagascar and place it in the best possible conditions for supplying profitably at least all the maize imported by France, which, in normal times, reached the round figure of 500,000 metric tons, but which, at present, is being imported in much larger quantities. Emphasis is laid on the necessity of organisation among the farmers to carry out this scheme.

161 - **Transplanting in the Control of "Wild" Rice in Italy.** — MARCARELLI, B., in *Il Giornale di Riscoltura*, Year VII, No. 21, pp. 260-264. Vercelli, November 15, 1917.

In the Italian rice-fields the name "riso-crodo" or "riso selvatico" (wild rice) is given to plants forming sub-varieties, now become wild, of the oldest variety of rice cultivated. They are characterised by: — vigorous growth from the beginning; the ease with which the grain drops from the panicles with the slightest contact; the vitality of the grain lasting many years. They are placed in two principal categories: — 1) with white panicles; 2) with red panicles. The first category, which is the more common and more dangerous because of the ease with which the grain falls when ripe, includes plants of medium growth, with white nodes, rather compact large panicles with round, bearded grain of a silvery white after earing and during flowering, but yellowish when ripe. The plants of the second category are less dangerous, because less common with little tendency to remain wild; they are straight, high, with black nodes, slightly hulled or bare grain, long and covered with a yellowish-red down. Since a few years there has spread more extensively another sub-variety, similar to that of the second category in size, but with long-bearded, black panicles, whose grain falls very easily and spreads quickly.

It is impossible to exterminate these plants by uprooting ("rimonde"), because, while green, they resemble cultivated rice very closely, and, after earing, they are very similar to "Ostiglia" and "Lencino" rice. It is for this reason that they are the cause of serious loss in permanent rice fields, a loss exceeding that caused by the most common weeds, sometimes affecting 70 to 80 % of the yield. Moreover, the few grains which pass into the crop decrease its value, for they break easily during threshing and, after polishing, have reddish lines.

When a rice field infested with "wild" rice has been under rotation for one or two years with meadow grass or wheat, and the turn of rice comes round again, the "wild" rice appears again, stronger than ever, because a large number of grains remain alive in the soil.

The methods recommended for the control of "wild" rice are. — Turning poultry on to the rice field immediately after the harvest; burning the stubble whenever and wherever possible; deep winter and spring ploughing; careful and continuous weeding of the field; collecting the panicles immediately after flowering; sowing in lines so that all plants growing in the spaces may be pulled up.

Nevertheless, all these methods are not always efficient for fighting or preventing the spread of the plants; but they disappear easily and quickly if the transplantation method is adopted. By this method, between two harvests of rice, may be obtained one of colza, crimson clover, hay or rye. The "wild" rice seeds which have shot up during this intermediate harvest ripen with great difficulty on account of the insufficient winter-spring temperature. The basis of this method is as follows: as soon as transplantation has been carried out, the level of the water must be raised from 5 to 30 cm., thus the "wild" rice remains too long out of contact with the air and rots. The few plants which survive are soon outstripped and overcome by the cultivated rice, and rapidly turn yellow and die.

The life cycle of "wild" rice is much affected, and completely stopped after two or three years of the transplantation method, which is the only efficacious one for eradicating this weed from new rice fields, or old or mountain ones.

**STARCH CROPS** 162 - **Tuber and Root Cultivation Trials made in 1916 at the Agricultural Station of Flahult, Sweden.** — VON FEILITZEN, HJALMAR, in *Svenska Mosskulturförenings Tidskrift*, Year XXXI, No. 6, pp. 469-486. Jönköping, 1917.

1) **COMPARATIVE EXPERIMENTS WITH 35 VARIETIES OF POTATOES.** — An average yield of 6.36 tons per acre was obtained, with a maximum of 11.15 and 10.35 tons per acre for Grahns Non Plus Ultra and the English potato, The Factor, respectively. The percentage of small tubers was fairly high — 20.7 % — as a result of the early autumn frosts which prevented full growth. In comparison with the starch percentages of 1915 and 1914 (15.4 and 15.1 %), that of 1916 was low, an average of 13.15 %, with a maximum of 14.56 and 14.18 % respectively for Makalös and Non Plus Ultra. The starch yield per acre was 3 569 lbs. for Non Plus Ultra, 3 186 lbs. for Juvel, 3 093 lbs. for Harbinger, and 3 038 lbs. for The Factor.

2) **ROOT CROPS.** — Turnips lead with 27.87 tons per acre (Weibulls Bortfelder and Svalöf Bortfelder); then come kohlrabi, with 9.15 tons, mangolds (Ovoïde des Barres), with 8.55 tons, and, lastly, carrots (Champion), with 4.77 tons per acre.

**FORAGE CROPS** 163 - **The Cultivation of Alfalfa in the Oasis of Tripoli.** — MAZZOCCHI-ALEMANNI, NALLO, in *R. Ufficio agrario della Tripolitania, La coltivazione dell'erbamedica nell'oasi tripolina* (Istruzioni pratiche agli agricoltori locali), Istruzione No. 1, pp. 18. Italian text + 2 figs. + pp. 10. Arab text + 1 coloured plate. Tripoli, 1917.

Alfalfa is undoubtedly the most important native irrigated herbaceous crop of the Tripolitan oasis, often it is the only one, and, at any rate, is the principal fodder of the draught animals, who usually eat it green.

The high yields obtained from alfalfa locally, far surpassing those of the best Italian irrigated fields, the good quality of the fodder, its high price, the absence or lack of other foods for livestock, and the absolute necessity for the native farmer to have an animal employed permanently on a certain kind of work, especially drawing water from the wells, are all factors which prompt him to give as much attention as possible to this crop.

In normal times preference is given to alfalfa (native name: "sofsa") rather than barley, which is grown on the steppes round the oasis, or received from the interior. The production of seed for the market is very limited, and its price very high. In 1917 the Royal Agricultural Office started to distribute seed free of charge, and, to improve the crop, issued practical rules (given in the paper under review) drawn up from observations made in the best alfalfa fields of the district.

The soil of the Tripolitan oasis is very well suited to the growing of alfalfa so long as it is well cultivated (deep and careful hoeing, weeding) and manured with: — 398.25 cwt. of manure; 20 cwt. of wood ash; 3.98 to 4.76 cwt. of calcium sulphate; 3.18 cwt. of superphosphate per acre. After harrowing down the soil, a network of small irrigation canals is constructed according

to the excellent native system, which consists of a series of main canals (usually of earth, rarely of stonework), arranged like fish-bones, and a certain number of secondary canals, also of earth, distributed over the whole area to be irrigated. The ground between two of these secondary canals is divided into a double row of plots ("gedaue"; *gedula* in the singular) measuring from 2 to 6  $\frac{1}{2}$  square yards, flooded separately by the water from the small secondary canals, each of which feeds a double row of plots, usually losenge shaped. Its well to surround the alfalfa field by hedges so as to protect it against the winds.

Local seed must be used. Repeated experiments with Italian and Tunisian seed always gave very bad results. There are two strains of native alfalfa: — "chobbesi" and "nefeh". The first gives higher yields and has larger leaves; the second has smaller leaves and lower yields. The most famed oasis localities for the production of good seed are Tadjourah and Al Aïoun (Menschiah). The seed from the former is excellent in all soil which have soft water; those from the latter are particularly suited to soil irrigated with slightly brackish water. The best time for sowing is between March and May. Alfalfa is also sown from October to November at the same time as barley. It is sown either in lines, in holes containing 3 or 4 seeds, or broadcast. In the last case, sowing must be followed by hoeing, and always by abundant irrigation.

Ten to fifteen days are allowed to elapse between the first and second irrigation, so as to allow the roots to penetrate deeper. The normal duration of irrigation is from 5 to 6 days during the hot season, and from 10 to 12 days, or even more, during winter. A depth of from 30 to 50 mm. of water is given at each irrigation. Weeding is very important. Manure is not usually given during the first year, but the following years liquid manure is added to the irrigation water. The first cutting is made from 42 to 48 days after sowing; the others follow each other at intervals of from 20 to 25 days in summer, and from 30 to 40 days during the cool season. Good local alfalfa fields will give at least 8 cuttings a year, normally 10, and sometimes even 12. Experiments carried out by the author gave yields of 88  $\frac{1}{2}$  tons of grass per acre, equal to 22  $\frac{1}{4}$  tons of hay. In special cases higher yields may be obtained. As a rule alfalfa is not dried, but fed green. In normal times the truss gathered on one "gedula" has an average value of 4*d.*

The seed is collected only in the third year, which is usually the last. After alfalfa any crop may be grown except pepper.

DISEASES AND PESTS. — The only cryptogamic disease observed so far is leaf rust (*Uromyces striatus*), which, however, has never attacked the fields to such an extent as to compromise the crop or to make curative measures indispensable. As a protection against Aphids it is advisable to spread fine ash and irrigate less, or else cut before maturity. In 1916 the presence of *Cuscuta* was observed, and again in 1917. It seems to have been introduced into the oasis by the use of stable manure from the army, where hay from Italy is used.

164 - **An Annual Variety of *Melilotus alba*.** - COE, H. S., in the *Journal of the American Society of Agronomy*, Vol. IX, No. 8, pp. 380-382. Washington, November 20, 1917.

This paper is a contribution from the Office of Forage-Crop Investigations, Bureau of Plant Industry, U. S. Department of Agriculture. *Melilotus alba* is a biennial plant. In the spring of 1916 *Melilotus* seed from various districts was sown at Redfield, S. Dakota and Fargo, N. Dakota. In these two districts, seed from Alabama gave about 5 % of plants which flowered and matured seed during the first year; these plants did not differ, in most respects, from the typical biennials, but they all died during the following winter. The principal difference between the plants which flowered the first year and the biennial plants lies in the root; that of the former is a typical taproot with no enlargement at the crown and no crown buds; that of the latter normally possesses these characters. On the 27th. January, 1917, 275 seeds of the annual plants were sown in pots in a greenhouse; plants were obtained which, by May 25th., measured 4.5 to 5.5 feet, and were in flower.

The white-flowered annual variety may very likely be found in other districts of the south of the United States than those mentioned. It would probably be of great economic value as a winter crop in the south of the Gulf States, and in the centre and south of the United States as a summer hay crop and for green manure.

The acreage under *M. alba* in the United States is rapidly increasing; the most serious objection is the difficulty of eradicating it by autumn ploughing. This difficulty may be overcome by using the annual variety.

165 - **The *Eragrostis* of the Argentine and Uruguay: Their Value as Fodder Plants.** - GIROLA, CARLOS D., in *Boletín del Ministerio de Agricultura de la Nación* (Extracto), pp. 20, figs 5. Buenos Aires, 1917.

This paper is a summary of the various works aiming at making known the species of *Eragrostis* in the Argentine and neighbouring countries, especially with respect to their fodder and agricultural value.

The following species are included in the herbarium of the Argentine Ministry of Agriculture, or described by various authors for the Argentine or for Uruguay: —

*Eragrostis airoides* — *atrovirens* — *bahiensis* — *brasiliiana* — *brasiliensis* — *calotheca* — *capillaris* — *ciliaris* — *diplachmoides* — *elegans* — *Eragrostis* — *expansa* — *flaccida* — *hypnoides* — *interrupta* — *lindmanni* — *longipila* — *lugens* — *major* — *megastachya* — *mexicana* — *microstachya* — *minor* — *Neesii* — *neomexicana* — *nigricans* — *orthoclada* — *pilosa* — *plana* — *poaeoides* — *polytricha* — *psammodes* — *purpurascens* — *refuscens* — *reptans* — *retinens* — *rosea* — *seminuda* — *striata* — *superba* — *triflora* — *tricholea* — *violae* — *verticillata* — *virescens*.

These species are found over a large area; the most common are *E. pilosa* and *E. lugens*, valuable fodder plants in ploughed land. They resist the most diverse climatic conditions, adapt themselves to all soils, but prefer clean ones, profit much from fertilisers, especially lime and phosphates, as was proved experimentally by the author. They are propagated by seed. As they do not grow very thickly they yield better when mixed

with other Gramineae and with Legumineae. The earliest are *E. lugens* and *E. pilosa*, followed by *E. major*, *E. poaeoides*, *E. mexicana* and *E. megastachya*; the others are less tender and, consequently, late. They are better suited to pasture than to hay, partly because they bear being grazed very well. The most tender, and, therefore, the most valued varieties, give an average yield of 2.58 tons of grass per acre, which is reduced to 0.79 tons of hay (some do not give half this yield); those which grow best yield from 2.78 to 3.18 tons of grass per acre, giving from 0.79 to 0.99 tons of hay.

Analyses made in the Laboratory of Agricultural Chemistry of the Ministry of Agriculture (Buenos Aires) gave the results shown in the appended table. The narrow food ratio of the Argentine *Eragrostis* hay, which shows them to be superior to natural meadow hay and ray grass hay, explains the preference cattle show for them.

166 - Important Range Plants: Their Life History and Forage Value. — SAMPSON, ARTHUR, W., in *U. S. Department of Agriculture, Bulletin No. 545*, pp. 63 + LVI plates. Washington, October 8, 1917.

The Forest Service of the United States Department of Agriculture, in co-operation with the Bureau of Plant Industry, undertook, in 1907, in the Wallowa National Forest (north eastern Oregon) a study of the forage plants of grazing land in order to determine the habits, requirements and life history of the more important species. By observing bands of sheep while they grazed, the plants preferred by them were ascertained. The relative value of each variety was determined by studying its abundance, distribution, time of flowering, aggressiveness, reproduction (both vegetatively and by seed), seed habits, palatability, food value at various times during the grazing season and ability to withstand trampling.

Though the results are largely based on observations in the high mountains of Oregon at altitudes between 5 500 and 8 000 feet, they should be useful in revegetating the range throughout the West, since many of the species described are widely distributed, and the genera represented are among

the most important of those of the Western ranges. The bulletin gives a description and a natural size photograph of each important species.

The appended Table gives the relative water requirements of the most important plants studied. The relative ability of the various species to withstand drought was ascertained by determining the amount of water remaining in the soil when the plant had wilted to a point from which it could not recover. For artificial determinations the plants were dug up, with the roots undisturbed in their own soil, particular care being taken to prune off as little of the root system as possible. The lump of soil was placed in a wire basket and put back into the hole made by digging up the plant. After the plant had regained its strength it was slightly raised in order to increase the rapidity of the drying process. For plants with deeply penetrating roots especially, the soil was sometimes dug away all round the plant, leaving in place only the central core of soil; when the plant had wilted completely the moisture was determined by taking two samples of the soil.

In order to compare habitat requirements, the species are grouped in three classes.

CLASS A. — Plants of high moisture requirements, living in saturated soil, such as open marshes, wet meadows and bogs.

CLASS B. — Plants of medium moisture requirement, in relatively heavy soils which are saturated during the early part of the season, but later contain a medium amount of water.

CLASS C. — Plants of low moisture requirement, in well-drained lands, open glades, and exposed situations.

The table shows about  $\frac{3}{4}$  ths. of the most valuable forage crops to be dry-land plants. The vegetation of wet lands is very luxuriant, but little appreciated by live stock and of low food value.

The data on the germinating capacity of the seeds (see Table) were obtained from the seed-testing laboratory of the United States Department of Agriculture.

In another table are given the time of flowering and that of the ripening to the seeds of 51 species for 3 consecutive years (1907, 1908, 1909). They show that the flowering period varies more than that of seed maturity. All species and conditions considered, the flower stalks are mainly produced between July 5th. and August 10th., and the seed matures between August 15th. and September 1st. These periods are influenced by physical factors, but far more so by the weakening of the vegetation due to overgrazing. The periods of flowering and ripening are thus retarded, and, in extreme cases, no flower stalks are produced, and the seed has little or no germinative power.

167 — **Composition and Improvement of the South-Western Ranges of the United States.** — See No. 188 of this *Review*.

168 — **Influence of the Time of Cutting on the Amount and Composition of the Hay Produced.** — See No 184 of this *Review*.

the most important of those of the Western ranges. The bulletin gives a description and a natural size photograph of each important species.

The appended Table gives the relative water requirements of the most important plants studied. The relative ability of the various species to withstand drought was ascertained by determining the amount of water remaining in the soil when the plant had wilted to a point from which it could not recover. For artificial determinations the plants were dug up, with the roots undisturbed in their own soil, particular care being taken to prune off as little of the root system as possible. The lump of soil was placed in a wire basket and put back into the hole made by digging up the plant. After the plant had regained its strength it was slightly raised in order to increase the rapidity of the drying process. For plants with deeply penetrating roots especially, the soil was sometimes dug away all round the plant, leaving in place only the central core of soil; when the plant had wilted completely the moisture was determined by taking two samples of the soil.

In order to compare habitat requirements, the species are grouped in three classes.

**CLASS A.** — Plants of high moisture requirements, living in saturated soil, such as open marshes, wet meadows and bogs.

**CLASS B.** — Plants of medium moisture requirement, in relatively heavy soils which are saturated during the early part of the season, but later contain a medium amount of water.

**CLASS C.** — Plants of low moisture requirement, in well-drained lands, open glades, and exposed situations.

The table shows about  $\frac{3}{4}$  ths. of the most valuable forage crops to be dry-land plants. The vegetation of wet lands is very luxuriant, but little appreciated by live stock and of low food value.

The data on the germinating capacity of the seeds (see Table) were obtained from the seed-testing laboratory of the United States Department of Agriculture.

In another table are given the time of flowering and that of the ripening to the seeds of 51 species for 3 consecutive years (1907, 1908, 1909). They show that the flowering period varies more than that of seed maturity. All species and conditions considered, the flower stalks are mainly produced between July 5th. and August 10th., and the seed matures between August 15th. and September 1st. These periods are influenced by physical factors, but far more so by the weakening of the vegetation due to overgrazing. The periods of flowering and ripening are thus retarded, and, in extreme cases, no flower stalks are produced, and the seed has little or no germinative power.

## FIBRE CROPS

169 - "Bate's Big Boll", an American Variety of Cotton Tested in Sicily. — PRESTIANNI, NUNZIO, in *Il Coltivatore*, Year I, XII, No. 30, pp. 271-273. Casale Monferato, October 30, 1917.

This paper gives the results of experiments carried out in Sicily since 1911 to find a variety well suited to the climate of the country and capable of yielding a product more abundant and of higher quality than that of "cotone nostrale" (local cotton-plant), cultivated since remote times in the districts of Sciacca, Menfi and Ribera (Sicily).

Among the varieties tested, an American one, *Bate's Big Boll*, proved valuable and steps are being taken to increase its cultivation. In 1915 the production of staple in the district was 1.968 tons, in 1916, 3.936, and in 1917 it must have been 9.84 tons.

The characteristics of the variety are:

A vigorous, pyramid-shaped, bushy plant, with strong, dark red branches; in fresh, deep soil it reaches a height of from 23  $\frac{1}{2}$  to 29  $\frac{1}{2}$  inches, and, on the average, in clay (non-irrigated) soils, a height of from 15  $\frac{3}{4}$  to 19  $\frac{1}{2}$  inches. The leaves are rather large, of a deep green colour, with, at the most, 3 oval acuminate lobes. The flowers are large and pink. The capsules are large, oval and round, with 4 to 5 cells and 32 to 34 tufts of staple. Ripening begins at the end of August and continues throughout October.

The average yield of unginned cotton in non-irrigated soils is from 6.16 to 7.16 cwt. per acre, the average yield of staple, from 38 to 39 % (33 % at the most for local cotton).

The staple is fairly strongly attached to the seed, of a creamish-white, not very lustrous, soft, of an average length of 27 to 29 mm., of average resistance, homogenous. Its commercial value is much above that of the local plants.

170 - The *Allanthus* (*Allanthus glandulosa*) as a Paper-Yielding Plant. — FEDELE, V., in *La Nuova Agricoltura del Lazio*, Year V, No. 118, p. 345. Rome, December 1, 1917.

Some years ago (cf. *Il Coltivatore*, No. 4, Jan. 24, 1909) the author, as a result of experiments he made, mentioned the ailanthus as an excellent paper-yielding plant. It has the advantage of growing well everywhere, even in arid or purely rocky soils. By pollarding every three years and keeping the crown about 3  $\frac{1}{4}$  to 4  $\frac{1}{4}$  feet above the ground the author obtained about 200 lbs. of wood, which yielded 44 % of an easily bleached cellulose of a quality suitable for paper pulp. In 1909, the author estimated the value of this cellulose at 8*d.* per quintal of wet material; at the present day that value has increased greatly. One acre may contain from 240 to 280 trees, which, under normal market conditions, would give a profit of £ 8 per acre every three years.

PLANTS  
YIELDING OILS

171 - *Plukenetia conophora* ("Ngart"), a New Oil Plant of the Cameroons. — See No. 138 of this *Review*.

172 - **The Importance of Sweet Sorghum.** — PIÉDALLU, ANDRÉ, in *Comptes rendus des Séances de l'Académie d'Agriculture*, Vol. III, No. 38, pp. 1091-1095. Paris, December 5, 1917.

The author, after having shown how old is the cultivation of sweet sorghum (*Sorghum vulgare* Pers., var. *saccharatum*), describes his experiments with this plant, which he has grown near Paris, and which has done well there, partly ripening its grain. When replanting the young plants he observed that the stems could be made to multiply by embedding or hilling up the seedlings. By this method he was able to obtain strong plants with 4 or 5 stems instead of one, each of which produced a panicle and, in August, reached a height of 6 feet, some even exceeding 8 feet.

The uses to which all the different parts of the plant may be put are described.

**STEMS.** — In the climate of Paris the sugar content is only 4 to 5 % of saccharose, without reducing sugars. According to the author, the uncrystallisable reducing sugars of sweet sorghum are derived from the fermentation of the stems before treatment. In southern countries the sugar content is from 10 to 15 % (1), with 2 to 4 % of reducing sugars. Some vine-growers of the south cultivate a small quantity of sweet sorghum to strengthen the alcohol content of the wine.

**STEM RESIDUES.** — With the abundant fibre of the plant the author succeeded in producing a good paper. Analysis showed the stem to contain 15 to 17 % of fibre, or 29 440 lbs. of stripped stems gave 2 metric tons of paper pulp per acre.

**LEAVES.** — A good food for rabbits, which the author fed on them, although poisoning of livestock has been reported from Egypt and the Indies caused by young or badly developed leaves containing a cyanogenic glucoside, dhurrine (2).

**ROOTS.** — May be used for making alcohol.

**GRAIN.** — The author obtained about 100 gm. of grain per plant. In the south this yield may be 200 to 300 gm.; 100 gm. of grain give 72 gm. of hulled grain and 28 gm. of glumes.

The grain, which has a large reserve of starch, nitrogen and fat, gives a brown flour with a good flavour which may be mixed with wheat flour for breadmaking (3). It may be used for feeding livestock.

**GLUMES.** — The author extracted a colouring matter, which he is studying. It is characterised by an orange-red colour in dilute solutions of strong acids, changing to violet with alkalis. A drop of this acid solution, added to water containing lime salts, gives a characteristic violet-pink lake. This colouring matter dyes wool and cotton grey with iron, violetgrey with copper, pinkish-violet with aluminium, more or less dark brown with alkaline bichromate. It also dyes leather.

173 - **Relation of the Transformation and Distribution of Soil Nitrogen to the Nutrition of Citrus Plants.** — MC BETH, J. G. (Physiologist, Soil Bacteriology and Plant Nutrition Investigations, Bureau of Plant Industry, U. S. Department of Agriculture), in *Journal of Agricultural Research*, Vol. IX, No. 7, pp. 183-252, 19 figs, XXX tables, bibliography of 14 publications. Washington, D. C., May 14, 1917.

The total nitrogen content of Californian Citrus lands is often low, and the quantity rendered assimilable through the natural processes of nitrification soon becomes inadequate to the needs of the plants unless it is maintained by the addition of commercial fertilisers, cover crops, manure, etc. On the other hand, the low rainfall of the districts in which citrus is grown, and the furrow system of irrigation practised, cause an uneven distribution of the nitrates in the soil, so that the solution of the nitrogen problem depends, not only on a knowledge of the factors influencing nitrification, but also on a knowledge of the forces controlling the distribution of nitrogen in the soil.

In order to solve these problems the author carried out at the Citrus Experiment Station grove at Riverside, Cal. a series of fertiliser and irrigation experiments with various quantities of ammoniacal and nitric nitrogen. He came to the following conclusions: —

A) FERTILISER. — 1) *Dried blood*. — Semi-arid soils often fail to nitrify dried blood when added in 1 % quantities, but invariably nitrify it when it is applied in quantities not exceeding those used ordinarily under field conditions. In the first case it often produces large accumulations of ammonia which do not occur in the second. Semi-arid soils to which has been added 1 % of dried blood may lose, during a six weeks' incubation period, 50 % of the nitrogen added. As they frequently give off a strong ammoniacal smell, this loss is probably largely due to the volatilisation of the ammonia. Ammonification or nitrification studies on semiarid soils to which 1 % of dried blood is added are of doubtful value, and may lead to erroneous conclusions.

2) *Green manures*. — These, especially the legume varieties, nitrify very rapidly; half of the nitrogen contained in the green plant tissues may be converted into nitrates in 30 days. They also form a valuable source of energy for the non-symbiotic nitrogen-fixing organisms.

B) IRRIGATION. — 1) The furrow system of irrigation often causes a very unsatisfactory distribution of the soil nitrates. In many Citrus groves more than  $\frac{2}{3}$  rds. of the nitric nitrogen in the top 4 feet of soil are found in the surface 6 inches, in which, owing to the frequent cultivation, few feeding roots are found. This system also frequently causes the formation of nitre spots (1), where, if the soil is heavily fertilised, as much as 1 % of nitrogen as nitrates may be found by surface scrapings. These spots, or salt crusts, attributed by HILGARD to rapid nitrification of the organic matter of the soil, by HEADDEN to the fixation of atmospheric nitrogen by nonsymbiotic bacteria, and by STEWART and PETERSON to the leaching of nitrates already in the soil, are, according to the author, rather to be attributed to the movement of water in the soil. Their characteristic brown colour depends on

(1) On the subject of nitre spots, see No. 129 of this *Review*. (Ed.)

many factors, of which the most important appears to be the deliquescent character of the calcium nitrate.

When the furrow system of irrigation is used the fertiliser should be ploughed down somewhat deeper than the land is cultivated, thus placing the food within reach of the feeding roots, because in the cultivated zone, the irrigation tends to carry it away from these roots.

Much nitric nitrogen is lost from citrus lands by leaching. The most effective way of preventing this loss is by growing a winter cover crop.

2) Basin irrigation or overhead irrigation give a more satisfactory distribution of soil nitrates than the furrow system. The first seems to give better results when combined with a mulching system. However, the rapidity with which materials rich in nitrogen decay would seem to make it inadvisable to maintain a constant mulch with these materials, as the nitrates produced would probably be much in excess of the needs of the tree, and much loss would result.

C) **MOTTLED LEAF** (1). — This disease is usually more marked in plots treated with large applications of commercial nitrogenous fertilisers, and is frequently (but not always) associated with a high nitric nitrogen content of the surface soil, a content which may be due to unfavourable conditions of the soil. An extremely variable supply of plant food and soil moisture may be an important factor in mottling. Mottled leaves usually have a higher moisture and nitrogen content than healthy leaves.

174.—**The Teak Trade of Siam.** — HANSEN, C. C., in *Commerce Reports*, No. 93, p. 275. Washington, D. C., 1917.<sup>1</sup>

FORESTRY

The teak forests of Siam are mainly located on the hillsides in the northern part of the Kingdom, some 500 miles from Bangkok. The teak trees are girdled and allowed to stand for several years before being felled, and the logs are then dragged to the nearest stream and floated down, reaching the sawmills at Bangkok, fully seasoned, in about 5 years from the time of girdling.

Teak logging is regulated by the Government, and only trees of 76.5 inches girth may be girdled. A Government counting station is located at Paknampoh, a village situated on the River Chao Phya, 155 miles from Bangkok. The average number of teak logs arriving at this station each year is estimated at 100 000, and in addition about 20 000 logs, cut from the forest region adjoining Burma, are floated to Moulmién.

The total annual output of cut teak of all grades amounts to roughly 55 000 loads of 50 cubic feet, but of first quality the yearly output would likely reach only about half of the above estimate. On reaching the sawmills the logs are usually squared and the first-quality squares are graded according to the British Admiralty specifications, and are designated "Europe first class".

Siam's total exports of cut teak of all sorts for the fiscal year ended March 31, 1916, and for the preceding year consisted of: —

(1) See R. 1916, No. 1225. (Ed.)

Cut Teak	1914-15		1915-16	
	Tons	Value	Tons	Value
Squares	34 422	\$ 1 338 535	30 980	\$ 1 124 195
Planks.	2 810	191 080	3 960	231 755
Shingles	345	12 550	238	8 130
Log and butt ends	857	24 175	1 051	36 620
Scantlings	7 247	249 240	10 313	368 145
Other	1 237	50 870	1 328	48 545
Total	46 918	\$ 1 866 450	47 870	\$ 1 817 390

Of the exports during 1915-16, most of the teak squares went to India, Hongkong took nearly half of the teak planks, the teak shingles went to Mauritius and Ceylon, most of the log and butt ends went to Hongkong, while scantlings were bought chiefly by India.

### LIVE STOCK AND BREEDING.

#### HYGIENE

175 - **Reaction Produced by the Intra-Palpebral Injection of Mallein.** — LANFRANCHI, A., in *Il Moderno Zootatro*, Series V, Year VI, No. 9, pp. 197-202, fig. 1. Bologna, September 30, 1917.

The diagnosis of glanders by means of the reaction produced by the intrapalpebral injection, proposed by the author in 1914, has been widely used, having been officially adopted for use in the Allied armies. As the author has applied it to a considerable number of cases, he has been able to make many observations, which have lead him to the conclusions given below.

If, on account of numerous reactions produced by intra-palpebral injections or for other causes, sclerosis of the conjunctive tissue is observed in the lower eyelids, the mallein should be injected into the upper eyelid.

In the case of a negative intrapalpebral reaction in subjects already tested several times by this method, and for which the period of the last intrapalpebral reaction is unknown, a minimum period of 15 days should be allowed to pass before repeating the injection. If this precaution is not taken, a subject still infected with the living organism may be thought to be free from glanders.

176 - **The Intra-Palpebral Reaction in the Diagnosis of Epizootic Lymphangitis** (1). — LANFRANCHI, A., in *Il Moderno Zootatro*, Series V, year VI, No. 10, pp. 217-225, fig. 5. Bologna, Oct. 31, 1917.

The clinical diagnosis of epizootic lymphangitis, although generally fairly easy, is, however, not always possible, and under practical conditions the microscope is not always available for identifying the characteristic RIVOLTA cryptococcus. For this reason, the writer has sought a sure method for diagnosing this infection, based on the so-called "allergic" local reaction, i. e., on a special state of specific hypersensibility of the affected subjects.

(1) See R. June, 1917, No. 561 and August, No. 731. (Ed.)

The test materials are prepared in the following manner:— to 1 part of pus, collected aseptically and known to be free from other microorganisms, 2 parts of ether are added; shake well, then leave to stand for 24 hours; the ether is then evaporated off on the water-bath; make up to the original volume with distilled water and leave to stand for 24 hours; then heat at 80° C on the water bath for 15 to 20 minutes and allow to cool; centrifuge for 20 to 30 minutes at 2000 to 3000 revolutions per minute; decant off the liquid part, which constitutes the vaccine to be used for inoculating in 2.5 to 3 cc. doses, according to the number of cryptococci in the pus used.

The injection into the eyelid is carried out in the usual way.

In healthy animals, or those infected with a disease other than epizootic lymphangitis, the injection gives rise to an oedema localised at the points of injection, or which at the most extends to the lower eyelid only. This oedema is produced in 1 or 2 hours after inoculation, attains its maximum between the 8th. and 10th. hours, then being slowly reabsorbed, and disappearing entirely after 20-24 hours. On the other hand, in animals infected with epizootic lymphangitis, the local reaction, which commences 2 to 4 hours after the injection, already extends, between the 4th. and 6th. hour, over all the lower eyelid, sensibly reducing the palpebral opening; the oedema spreads gradually and, after 24 to 48 hours, reaches the lower border of the zygomatic crest, passes it a little in front whilst progressing backwards towards the lower mandibular arch, which it may even reach. This local reaction lasts several hours, then slowly diminishes up to the 3rd., 4th. or 5th. day. The purulent conjunctivitis occurs 4 hours after inoculation and increases in 24-48 hours.

One test for the intra-palpebral reaction has no influence on successive tests. The most intense and lasting effects of the reaction are shown by animals in which lesions have already commenced.

The use of this method of diagnosis, combined with treatment by arsivan, which was tested by FAVERO (*Moderno Zootiatro*, Scientific Part, 1917, No. 6, p. 129), who suggested its use, would, thinks the author, cause the disappearance of the centres of infection from which the disease spreads.

**177 - The Treatment of Epizootic Lymphangitis (1) by Means of the Autolysed Extract of Yeast.** — NICOLLE, M., FAYET and TRUCHE, in *Comptes rendus des Séances de l'Académie des Sciences*, Vol. CLXV, No. 27, pp. 1114-1115. Paris, December 31, 1917.

To fight against epizootic lymphangitis, caused by the cryptococcus discovered by RIVOLTA in 1873, an organism very close to the yeasts, the authors have tried *group antigenotherapy*. In beer yeast, they have found a cheap and efficacious therapeutic agent. Used unchanged, after the action of alcohol-ether, it remains without effect and causes abscesses, caused by the great resistance of the cell walls. Used as an autolysed extract, which the authors propose to call "*rivoltine*", it is quite successful, causing no ill effects. In this way is given a mixture of antigens, some of which are evidently identical with these of the cryptococcus.

(1) See *R.*, August, 1917, No. 734, (Ed.)

To prepare the juice, pressed yeast is autolysed for 24 hours at 37° C. in chloroform vapour; it is then centrifuged the supernatant liquor filtered off, phenol added; the liquid is then sealed up in small phials.

After describing the excellent results of their experiments, the authors advise the following technique:

At first inject 2 cc. (under the skin of the neck) to test the sensibility of the subject; after 4 to 8 days increase the dose to 5 cc., according to the case; after another 8 days, give 10 cc.; it may be advisable to give one two subsequent injections of 10 cc.

At present, the authors are considering how to deal with possible failures and how to decrease the length of the treatment.

178 - **Leucocytotherapy; or Aseptic Pyotherapy; Its Use in Certain Cases of Equine Lymphangitis.** — BRIDÉE, J., in *Comptes rendus des Séances de l'Académie des Sciences*, Vol. CLXV, No. 27, pp. 1121-1123. Paris, December 31, 1917.

Two authors, MM. BELIN and VELU, have, independently of one another, carried out successful experiments on the use of pyotherapy in the treatment of epizootic lymphangitis of the horse; pus obtained from the lymphangitic lesions is diluted in ether, then in water physiologically phenolated; the diluted pus is injected under the skin or in the jugular vein of the diseased horses, at intervals of a few days and at doses varying between 2 to 6 cc., corresponding to 0.2 to 0.6 cc. of initial pus.

These authors believe that the action of the pyotherapy is due to specific organisms contained in the pus: to the cryptococci. They consider the dilution of the pus as a "pyovaccine", and the method of treatment as "vaccinotherapy" derived from the WRIGHT method.

However, M. VELU has shown recently that the pyovaccine has not a strictly specific action and that it is efficacious in affections having no connection with epizootic lymphangitis (fistulae, various suppurations), and M. BELIN has successfully employed the method against ulcerous lymphangitis by using the pus produced by that affection; yet, in ulcerous lymphangitis, the pus often contains a very limited number of microorganisms.

These two facts attracted the author's attention and he asked whether the efficacious action of the pus was due, not to the specific organisms they contained, but rather to the leucocytes and remains of leucocytes that they contained; whether, in other words, the same satisfactory results could not be obtained by injecting absolutely aseptic pus, like that of "fixation abscesses".

Experiments on this subject were carried out by treating horses suffering from ulcerous or epizootic lymphangitis with aseptic pus obtained by injecting oil of turpentine under the skin of the horse's thorax, and removing, after 4 or 5 days, pus from the abscess thus caused and mixing it with water physiologically phenolated.

The author has obtained, by injecting aseptic pus, results quite comparable with those published by MM. BELIN and VELU. He concludes that pyotherapy cannot be included under "vaccinotherapy" and that its action is due to the leucocytes of the pus and their products.

"Aseptic pyotherapy" might be employed to advantage in equine lymphangitis and in affections where pyovaccines have already proved useful. It may be that it will find a much wider application.

179 - **The Poisoning of a Horse Caused by Eating *Paspalum distichum* Parasitised by *Ustilagopsis deliquescens*.** — HUE, ENRIQUE, in the *Anales de la Sociedad rural Argentina*, Year I, II, Vol. XXXI, pp. 602-603. Buenos Ayres, October, 1917.

It has been known for some years that *Paspalum* (1) is poisonous to animals; thus, MEUZE (*Handbuch der Tropenkrankheiten*, 1913) showed that the bitter variety of *P. scrobiculatum* is poisonous. In the Argentine, similar constations have been made by: RIVAS and ZANOLLI (*La tembladera*, IV Congreso Científico celebrado en Santiago de Chile, 1909); QUEVEDO (*La enfermedad de los rastrojos*, *Revista zootecnica*, No. 28, 1911; *Paraplegia enzoótica de los ovinos* (2), *Ibid.*, No. 33, 1912; *La pataleta*, *Ibid.*, No. 37, 1912; *Estudio de un Aspergillus patógeno*; *Agronomía*, No. 8-9, 1912; *Paraplegia enzoótica de origen digestivo*, *Boletín del Ministerio de Agricultura*, Vol. XVII, No. 6, 1914; *Notas sobre una nueva enfermedad de los equinos*, *Gaceta rural*, 1914; etc.); QUEVEDO and LIGNIÈRES (*Enfermedad tetaniforme epizootica de los bovinos*, *Boletín del Ministerio de Agricultura*, 1913); MOSCONI (*Paraplegia de los equinos*, *Revista zootecnica*, No. 34, 1912); ACOSTA (*El Huecú*, Thesis, Buenos Ayres, 1914).

The author found that 2 kg. of dry *Paspalum distichum* strongly parasitised by *Ustilagopsis deliquescens*, when given to a horse, caused paraplegia after 2 days, paralysis and death after the 3rd. day. A post-mortem examination showed the cause was poisoning. Another horse, given 10.6 kg. of *P. distichum* slightly parasitised, collected near Buenos Ayres, showed no morbid symptom whatever.

In intravenous injections in the pigeon, a 10 % decoction of the excrescences produced on the host plant of *Ustilagopsis deliquescens* in a 5 cc. dose, and a 10 % maceration in a 2 cc. dose, proved quite harmless.

180 - **Study of *Bacterium Pullorum* Infection.** — PAGE, J. B., in the *Twenty-ninth Annual Report of the Massachusetts Agricultural Experiment Station. Public Document* No. 31, pp. 89a-91a. Boston, 1917.

During the years 1916 and 1917 the studies on bacillary white diarrhoea of pullets have been carried out at the Massachusetts Experiment Station along the lines established. The object of the work has been to improve methods in diagnosis, to explain reasons for symptoms in certain avian diseases at present but little understood and to aid in formulating methods for prevention and control.

The work was divided in three parts:

1) Specificity of *B. pullorum* antibodies, with special reference to the agglutinins.

2) Toxins elaborated by *B. pullorum* and their relation to specific conditions in adult birds.

(1) See R., 1917, Nos. 829, 924, 1179. — (2) See R. Nov. 1917, No. 1035. (Ed.).

3) Investigations concerning the production of antibodies, with special reference to potency and rate of production.

I. — The work concerning the specificity of *Bacterium pullorum* agglutinins has been continued since 1915, as have tests and procedures concerning the use of 25 strains of this organism isolated from birds in the State of Massachusetts. Recently, more than 10 new strains have been added to this list. The data obtained and that being accumulated will relate to thorough tests of the agglutinins elaborated by animals and birds against *B. pullorum*, particularly with cultures of the *B. coli*, *B. typhi*, *B. dysenteriae* group. At the present time 21 adult birds are immunized against *B. pullorum* and are producing definite agglutinins. Fourteen rabbits also are used for these studies, having been immunized and hyperimmunized during the past year.

II. — Up to the present a toxin which is suitable for carrying on progressive work has not been found. Definite studies, however, are under way toward this end. The results up to date show beyond a doubt that the toxin is endotoxic and also that it is most intimately connected with the bacterial cell. It is hoped that these studies will lead to an explanation of its action in relation to some of the paralytic conditions in adult birds, which in the last few years have been so common in the State of Massachusetts.

III. — The investigation concerning the production of antibodies, with special reference to the potency and rate of production, was started in August 1916, and agglutinins artificially produced. Blood from this stock has been studied, and now attempts are being made to study the progeny this year to determine the potency of agglutinins elaborated in birds descended from stock known to have definite infection experimentally produced. These studies are to be continued, with the hope that they will show the rate of production, and demonstrate why young pullet blood testing has not given as universally satisfactory results as the blood testing of birds that have laid eggs and have ovaries capable of complete function. This problem has direct bearing on the routine work of testing breeding flocks for indications of *Bacterium pullorum* infection.

ANATOMY  
AND  
PHYSIOLOGY:  
GENERALITIES

181 — Studies on the Duration of Life: Temperature Coefficients and Influencing Factors. — I. OSTERHOUT, W. J. V., Some Aspects of the Temperature Coefficients of Life Processes, in the *Journal of Biological Chemistry*, Vol. XXXII, No. 1, pp. 23-27, 1 fig., 2 tables. Baltimore, October, 1917. — II. LOEB, J. and NORTHRUP, J. H., On the Influence of Food and Temperature upon the Duration of Life. *Ibid.*, pp. 103-121, 6 fig., 13 tables. — III. NORTHRUP, J. H., The Effect of Prolongation of the Period of Growth on the Total Duration of Life, *Ibid.*, pp. 123-126, 1 table.

I. — In most life processes the substances formed at a given moment are broken down suddenly. If the reaction forming the substance has a different temperature coefficient from that which destroys it interesting conditions may arise. The author has made a mathematical study of the relations of these coefficients.

II. — In order to find out the nature of the causes determining the natural duration of life of metazoa, a quantitative method is required which

will permit the duration of life to be represented as the numerical function of one variable. Taking as a basis the fact that, in this case, chemical conditions in the organism are one of the main variables, attempts were made to determine whether there were a definite temperature coefficient for the duration of life, and whether this coefficient were of the order of magnitude of that of a chemical reaction. The first experiments, made on fertilised and unfertilised eggs of the sea urchin, could only be carried out at the upper temperature limits of the organism, because, at ordinary temperatures, this organism lives for years. It was, therefore, necessary to use a form whose duration of life was short enough to measure the duration of life, even at the lowest temperatures; insects are specially fit for this purpose. As METCHNIKOFF had pointed out that bacterial poisoning may shorten the duration of life, "aseptic" (*i. e.* microorganism-free) fruit flies (*Drosophila*) were chosen.

Previous experiments made by the authors had shown that, with a proper and adequate supply of food, the duration of the larval, pupal and imago stages are each an unequivocal function of the temperature, and that the temperature coefficients for each stage are approximately identical, and are of the order of magnitude of that of a chemical reaction, *i. e.* about 2 or more for a difference of 10°C. The experiments described deal with the two main factors determining the duration of life: 1) food supply; 2) temperature. All were carried out with flies rendered "aseptic" by a combination of the methods of BOGDANOW-DELCOURT and GUYENOT.

1) INFLUENCE OF DIFFERENT KINDS OF FOOD. — The period of growth is limited to the larval stage. Larvae cannot grow on glucose-agar unless yeast is added, whereas the imago can live without yeast. This difference may be due to the fact that the larva requires food for the synthesis of the compounds of its body, whereas the perfect insect, which does not grow, can do without such accessory substances, or needs them in such small quantities that they can be supplied by the hydrolytic processes within its cells.

The flies from the larvae fed on yeast were placed on different culture media immediately after hatching. It was found that, at 25°C., flies fed on agar alone or on agar with the necessary salts lived less than 2 days; when dextrose and salts were added to the agar they lived over 8 days, and on glucose-agar they lived 28.5 days. At 30°C. the flies lived as long on glucose-agar alone as when yeast was added (see Table I).

TABLE I. — *Effect of food on the duration of life of the imago (both sexes).*

Food	1 gm. washed agar + 100 cc. water	1 gm. agar 0.1 gm. $K_2HPO_4$ 0.1 gm. $MgSO_4$ 100 cc. $H_2O$	1 gm. agar 0.1 gm. $K_2HPO_4$ 0.1 gm. $MgSO_4$ 2.0 gm. dextrose 100 cc. water	Glucose agar		Glucose agar + 6 gms. yeast per 100 cc.

2) INFLUENCE OF TEMPERATURE. — *Larval period.* — The aseptic cultures, in Erlenmeyer flasks, were kept in water-jacketed incubators regulated to  $\pm 0.1^{\circ}$  C. and containing water so that the humidity was always about 100 %. The eggs from the aseptic insects were put in the incubator and hatched very soon after they were laid. The duration of life of the larvae was reckoned from the time the eggs were placed in the incubator till the time the pupae were formed. Six to ten cultures were

made for each temperature. Temperatures less than 10°C. could not be used, since the larvae do not hatch below that temperature. The results (see Table III) clearly show the influence of temperature.

*Pupal stage.* — A similar influence is noticed on the duration of the pupal stage, calculated from the formation of the pupa to the emergence of the winged insect.

*Imago stage.* — A similar influence.

To sum up, temperature influences the duration of all three stages, and, consequently, the total life duration of the fruit fly. (See Table IV).

III. — A third series of similar experiments showed that a prolonged period of growth prolongs the total duration of life. It has been seen that, in the case of the "aseptic" *Drosophila*, growth may be greatly retarded by absence of yeast. The prolongation of the larval stage affects neither the duration of the pupal stage nor (as is shown by these last experiments) that of the imago stage. This proves the relative duration of each of the three stages to be independent of that of the other two stages; this coincides with the hypothesis that the duration of each of these stages is determined by the formation or disappearance of a definite specific substance.

TABLE IV. — *Influence of temperature on the total duration of life (Drosophila).*

182 - Physiological Effect on Growth and Reproduction of Rations Balanced from Restricted Sources. — HART, E. B., MC COLLUM, E. V., STEENBOCK, H. and HUMPHREY, G. C., in the *Journal of Agricultural Research*, Vol. X, No. 4, pp. 175-198 + Plates 18-32. Washington, D. C., July 23, 1917.

This paper summarises the results of further studies on the physiological value of restricted rations. The early work of the writers (1) demonstrated clearly the inadequacy of the accepted theory as to what constitutes a balanced or complete ration. Up to that time total protein (without reference to quality), energy, and ash materials were considered the essentials of a ration. The latter, however, occupied no position in the expression of the standards developed which have been stated only in terms of total digestible protein and energy. It is, however, probably

(1) MC COLLUM, E. V., STEENBOCK, H. and HUMPHREY G. C., *Idem*, in *Wisc. Agr. Exp. Sta. Res. Bul.* 17, pp. 131-205, 24 fig. Madison, Wisc., 1911.

true that, in a practical sense and with the generally accepted knowledge of the quality of feeding materials accumulated from a long and varied experience, such standards have had and will continue to have very great value; but their limitations are also made evident by this earlier work of the writers and are emphasised by what they have since done.

To day a ration can be considered complete and efficient only when it contains protein of adequate quantity and quality, adequate energy, ash materials in proper quantity and proportion, and two factors of unknown constitution (vitamines) which the writers have designated as "fat-soluble A" and "water-soluble B". In addition to these normal factors, there may be introduced with natural foodstuffs the important factor of toxicity. This can be wholly absent or so mild in its effects as to be entirely obscured when the other essentials of a ration are at an optimum adjustment.

#### EXPERIMENTAL WORK STARTED IN 1910 ON WHEAT AND CORN RATIONS.

— In order to locate the deficiencies of the all-wheat-plant ration (wheat grain, wheat gluten, and wheat straw), which had given fair growth, but was a failure in reproduction with grade Shorthorn heifers, a new series of experiments was again started in 1910, using for the purpose vigorous grade Holstein heifers of initial weights of from 200 to 400 pounds. It was also proposed that one group should receive its nutrients wholly from the corn plant, another from the wheat plant, a third from corn grain and wheat straw, a fourth from wheat grain and corn stover, while a fifth group should receive its nutrients from corn grain with the roughage equally divided between alfalfa hay and wheat straw. These rations were closely comparable in digestible proteins and net available energy and were balanced in the ordinary sense of the standards. The animals were fed what they would consume of this mixture and, in addition, received common salt and natural water. They were allowed a daily run to an outside paddock free from all vegetation. Their records of growth and final status are given in Table I.

Restriction to the wheat plant as a source of "balanced" nutrients did not sustain the growth of the heifers. Such animals also failed to show oestrus and could not be bred. Marked pathological conditions resulted, such as blindness, feeble and emaciated condition, and abnormal excitability followed by collapse. The critical factors in this ration were poor mineral content and toxicity. This statement is based on records made by other animals of this species and on records with rats and swine.

In contrast to the all-wheat-ration group stood the all-corn-ration group. The latter not only showed continuous growth, but became physiologically active and produced strong calves. The decline in weight at the end of two years shown by No. 575 was due to slow recovery after calving.

By the use of corn stover as a roughage in place of the wheat straw, growth was sustained but reproduction was only partially successful, dependent upon the stamina of the mother. Where reproduction was successful in the first gestation period, it failed in the second, owing to the cumulative effect of the wheat toxicity.

By the use of alfalfa hay to take the place of one-half of the wheat

straw, results similar to those with corn stover were secured. Growth was splendid, reproduction normal in the first gestation period, but weakness appeared in the second gestation.

TABLE I — *Record of Growth of Holstein calves 1910-1912.*

No. of Animal	Ration	Weights in pounds					Condition after 2 years
		Initial (June 2, 1910)	After 6 months on ration	After 1 year on ration	After 18 months on ration	After 2 years on ration	
629	Ground wheat, 8 pounds						
	Wheat gluten, 0.3 pounds	377	655	569	610	452	Miserably emaciated.
639	Wheat straw, 5.7 pounds						Do.
	do	406	722	683	630	519	
637	Wheat grain, 6.7 pounds						
	Wheat gluten, 0.3 pounds	206	369	533	656	790	Fairly strong.
641	Corn stover, 7 pounds						
	do	207	377	594	783	820	Do.
575	Corn meal, 5 pounds						
	Gluten feed, 2 pounds	349	664	970	1139	974	Strong and vigorous.
594	Corn stover, 7 pounds						Do.
	do	270	496	735	905	923	
635	Corn meal, 5 pounds						
	Gluten feed, 3 pounds	208	301	480	591	690	Poor growth and poor condition
636	Wheat straw, 1 pounds						Do.
	do	220	384	541	684	642	
942	Corn meal, 5 pounds						
	Gluten feed, 2 pounds	—	613	686	911	1161	Strong and vigorous
643	Wheat straw, 3.5 pounds						
	Alfalfa Hay, 3.5 pounds	—	537	602	800	788	Do

The alfalfa and corn stover introduced a better salt mixture, a little different protein mixture, and probably a more plentiful supply of growth-promoting substances, all of which, according to the writers' hypothesis, would either individually or collectively improve the ration but not necessarily make it perfect. It might still fail if the mass of toxicity was too large.

Baking the wheat grain did not improve it. The particular effect of these all-wheat-grain rations was to cause marked histological changes in the nervous tissues of the offspring. The motor cells partly degenerated and the spinal cord showed a more or less oedematous condition. This was analogous to the writers' observations on swine with wheat-grain feeding. On wheat-grain and wheat-straw rations growing heifers also showed symptoms of nerve degeneration, as evidenced by blindness and great excitability. The cause of the disturbance was due to the inherent toxicity of the wheat grain and not to "deficiencies of vitamins".

Corn grain plus wheat straw allowed sustained growth, but at a slow rate. The offspring were weak or dead. Addition of salt to this ration made it normal, indicating that this was the only factor needed for perfect nutrition with this ration.

A physiologically complete ration such as the corn-grain and corn stover mixture could not be disturbed, at least in a single gestation, by

altering the calcium-magnesium ratio through the addition of magnesium salts. Even the addition of mineral acids to this ration, in such quantities as to make the urine of the individuals receiving it acid to litmus and rich in ammonium salts, did not disturb its nutritive completeness.

The addition, however, of wheat embryo to a corn ration did cause disturbances, bringing about early abortions. This was due to its high content of the toxic material of the wheat kernel.

Considering the influence of these investigations on practice, the writers point out that there is already much trouble with reproduction by cows in the Dakotas, wherever much wheat straw is fed with corn grain. In many cases where the breeding stock was only fed wheat grain and certain roughages, the calves were born either dead or weak, with great financial losses to many breeders. No one would have suspected that the ration was a factor in these disasters, but it undoubtedly was the direct cause of the trouble.

The data presented include also the study of the influence of these factors on milk secretion.

183 — On the So-Called Specificity of the Abderhalden Reaction. — BOLDYREFF, W. N., in *Comptes Rendus des Séances de la Société de Biologie*, Vol. LXXX, No. 18, pp. 882-884. Paris, November 24, 1917.

The ABDERHALDEN reaction is based on the fact, as yet unproved, that the ingestion of albuminoid substances causes the appearance of specific proteolytic ferments in the blood.

For 16 years, the author, in collaboration with M. J. KNIAZEFF, has has been carrying out researches on the work of digestion, as distinct from digestion. These researches, which have been carried out on 10 persons, hundreds of dogs, cats and birds, throw new light on the ABDERHALDEN reaction.

Contrary to general belief, the stomach and the intestine with its glands do not remain inactive after digestion; on the contrary, these organs carry out a well defined and intense work which is regularly interrupted by periods of complete repose. This activity of the stomach and of the intestine with its glands, which takes place during fasting, has been called "periodic work of the digestive apparatus apart from digestion". This is what takes place: the animal being fasting, and the gastric glands quite inactive, from time to time, with the regularity of clockwork, the pancreatic and intestinal glands as well as the gall-bladder, produce a secretion; this secretion is accompanied by intense rhythmic contractions of the stomach and small intestine.

This simultaneous "work" of the organs in question lasts from 20 to 30 minutes in the dog, and a little longer in man; the consecutive phase of "rest", which affects all the organs in question at the same time, lasts about an hour in the dog, and a little less in man.

During each period, 25 to 30 cc. of a mixture of digestive juices can be withdrawn from the duodenum of the dog, and 50 to 60 cc. from that of man. These juices contain abundant intestinal ferments that act on albu-

minoids, fats and carbohydrates; they are afterwards absorbed without change in the small intestine and never reach the large intestine.

Experiments by M. KNIIZEFF and the author have shown that these ferments, one of which is a proteolytic ferment, penetrate, during the period of "work", into the blood, where they can be easily demonstrated. During the "rest" periods the ferments in question disappear from the blood. These appearances and disappearances take place with the greatest regularity, a fact that forms the first cause of error in the ABDERHALDEN reaction.

The second error is as follows: If the blood of a man or woman is examined during the period of work of the digestive apparatus, it is found that the ABDERHALDEN reaction gives a positive result with any albuminoid substance (placenta, lungs, fibrin, etc.) On the other hand, if blood be examined that has been obtained during the rest period from the same subject on the same day, the ABDERHALDEN reaction always gives a negative result, even with gravid females.

As this reaction is not specific, the author concludes, it has no diagnostic value, but it is very useful for showing the presence of proteolytic ferments in the blood.

184 - Influence of Date of Cutting on the Food Value of Hay; Experiments carried out in Denmark. — KAISTEN, IVERSEN and KRISTENSEN, R. R., in *Tidsskrift for Planteavl*, Vol. XXIV, Pt. 3, pp. 405-435. Copenhagen, 1917.

FEEDS  
AND FEEDING

The experiments described were carried out at the agricultural School of Naesgaard in order to determine to what extent the date of cutting influences the composition and yield in hay of clover, either alone or mixed with fodder grasses. The dates of the first cutting were: June 16, when the clover began to flower; June 26, when the clover was in full flower and the grasses began to flower; July 9, when the clover had already partly lost its flowers.

QUANTITY OF FODDER. — The date of the first cutting seems to have no influence on the *total* yield of the three cuttings; the third cutting diminishes in quantity with the later date of the first cutting.

TABLE I. — Relation of quantity of hay to the date of the first cutting.

1st. cutting		2nd. cutting		3rd. cutting		Total Cwt.
Date	Cwt.	Date	Cwt.	Date	Cwt.	
June 16.	52.70	August 9.	24.98	October 15.	8.10	86.00
June 24.	52.62	August 15.	28.32	October 15.	6.98	87.98
July 9.	55.24	September 11.	30.88	October 15.	1.72	87.90

CHEMICAL COMPOSITION. — This is shown in Table II; the moisture content is 15% for all samples.

TABLE II. — *Composition of hay cut at different dates.*

	Early cutting	Late cutting
Albuminoids . . . . .	10.2	8.5
Fat . . . . .	2.6	2.5
Fibre . . . . .	20.0	22.1
Nitrogen-free extract. . . . .	30.8	31.0
Pentosans . . . . .	13.3	14.0
Ash . . . . .	8.2	6.8
Moisture . . . . .	15.0	15.0

Hay cut early is distinguished by its high albuminoid content and by its ash percentage, whereas it is relatively poor in fibre and pentosans.

EXPERIMENTS WITH DAIRY COWS. — The date of cutting does not influence the composition of milk, but influences its production to a marked degree; with 200 lbs. of hay cut early 16.28 lbs. more milk were obtained than with an equal quantity of hay cut late.

EXPERIMENTS ON THE GROWTH OF CALVES. — The experimental animals were divided into three groups. Care was taken to choose calves of equal age and weight so that an increase in weight could be with certainty attributed to the hay. The most important results are summarised in Table III.

TABLE III. — *Experiments with calves fed on hay cut at different dates.*

Increase in weight each 10 days			
	Early cutting	Normal cutting	Late cutting
	lbs.	lbs.	lbs.
Year 1913. 1st. period. . . . .	12.28	11.44	10.78
Year 1913. 2nd. period. . . . .	11.66	10.56	9.68
Year 1914. 1st. period. . . . .	10.56	9.46	7.92
Year 1914. 2nd. period. . . . .	13.42	10.78	8.80
Year 1915 . . . . .	8.68	—	6.38
Averages of 4 experiments 1913, 1914. . . .	12.10	10.56	9.24
Averages of 5 experiments 1913, 1914, 1915.	11.44	—	8.80

During a period of 100 days the following increases in weight were obtained: — hay cut early, 121.00 lbs.; normal hay, 107.80 lbs.; hay cut late, 92.40 lbs. The early hay, therefore, gives the best results.

DIGESTIBILITY. — These experiments were carried out with two animals fed exclusively on hay cut early and hay cut late.

The greater digestibility of early-cut hay and its greater number of calories explain the higher production of milk and more rapid growth of the calves.

TABLE IV. — *Digestibility of hay according to the date of cutting.*

	A) Early cutting	B) Late cutting	Difference A-B
	%	%	%
Dry matter . . . . .	60.8	53.7	7.1
Protein . . . . .	72.6	60.9	11.7
Pentosan . . . . .	60.6	54.1	6.2
Fibre . . . . .	53.2	46.3	6.9
Ash . . . . .	42.4	34.8	7.6

185 — **The Feeding Value of the *Eragrostis* of the Argentine.** — See No. 165 of this *Review*.

186 — **The Insufficiency of Maize as a Source of Protein and Ash for Growing Animals.** — HOGAN, ALBERT G. (Department of Chemistry, Kansas State Agricultural Experiment Station, Manhattan, U. S. A.), in the *Journal of Biological Chemistry*, Vol. XXIX, No. 3, pp. 485-493, 3 diagr. Baltimore, Apr. 1, 1917.

Agriculturalists have known for a long time that maize kernel does not suffice as a diet for growing animals. Experiments on young rats have shown the first limiting factor for growth to be a lack of certain inorganic constituents. When the mineral deficiencies were corrected normal growth was not obtained, even after the addition of considerable quantities of purified protein, thus proving a lack of suitable growth accessories. According to MC COLLUM, and his collaborators, maize kernel is lacking in an accessory, called by them "fat-soluble A". (1). The author's previous experiments show that mineral deficiencies in maize are tolerated much better by swine, and protein deficiencies are tolerated better by rats. Assuming that maize is poor in one or more of the growth accessories, swine are much less affected by it than are rats.

The author has continued his earlier work in order to determine specifically what inorganic elements in the ash, and what amino-acids in the proteins are deficient in quantity, thus constituting limiting factors. It was first shown that the addition of tryptophane and lysin improved the proteins of maize, and later, that tryptophane is the first limiting factor in the proteins of the maize kernel, and that lysine is the second. The most important mineral deficiency of maize is calcium.

187 — **The Effects of Feeding Calcium Chloride to Domestic Animals (2).** — LOEW, O., in *Mitteilungen der Deutschen Landwirtschafts-Gesellschaft*, Year XXXIII, No. 37, pp. 591-594, Tables 3. Berlin, September, 1917.

The rational use of calcium chloride in feeding domestic animals gives good results, both in increasing the general production as in improving an unhealthy condition. These results are very useful, especially when the relatively small amount of chloride required and its low price are considered.

(1) See R. Jan., 1918, No. 2. — (2) See R. 1915, No. 406 (Ed).

The writer analyses the effects produced, and collates the results obtained by various workers for horses, cattle and pigs.

**HORSES.** — An experiment was made by THUNN on 7 full-grown horses affected with gastric and cardiac troubles. Their daily ration was made up of 1 kg. of oats, 750 gm. of whole maize, 1250 gm. of raw sugar and 7 kg. of hay, plus a daily dose of 30 gm. of crystalline calcium chloride dissolved in 250 gm. of water. The experiment lasted from March 6 to May 29, 1916. During these eight weeks the animals showed a noteworthy increase in live-weight (see Table I), as well as an improved state of health. Calcium chloride cures animals of bad habits such as crib-biting, licking the walls, eating sand, etc. — habits that appear to show the lack of some necessary element in the food and also prevents other troubles, such as exostoses, so common in young horses. The results are all the more evident, the lower the calcium content of the food. It is thus desirable to take account of the abundance or lack of lime in the food given; the minimum content is 10 gm. of lime per kg. of hay. Very often this amount is not reached; in addition, pastures on soil poor in lime, manured only with kainit, superphosphates or basic slag, can only produce a defective food, often producing deformed front legs, exostoses, etc. (WEYGOLD).

TABLE I. — *The effect of calcium chloride on the growth of horses.*

Names of the horses	Weights found during the experiment							Increase in weight at the end of the experiment
	March 6th.	March 20th.	April 3rd.	April 17th.	March 1st.	May 13th.	May 29th.	
Patron . . . . .	475 kg	482 kg	484 kg	495 kg	495 kg	497 kg	—	22 kg
Luzia . . . . .	—	462	473.5	480.5	494.5	496.5	—	34.5
Schleier . . . . .	—	354	370	377	372	360	364 kg	10
Salome . . . . .	—	407	407	416	424	479	—	17
Nusshäher . . . . .	—	400	401	402	403	412	414	14
Rektor . . . . .	—	—	383	376	389	394	413	29
Nichte . . . . .	—	—	367	369.5	381.5	393.5	—	26

**CATTLE.** — Calcium chloride also produces good effects on the general growth and milk production. A group of 10 cows and 2 sick young animals were experimented with for 28 days by HOFUKE. The daily dose was from 0.02 to 0.04 gm. per kg. live weight for the cows and from 0.01 to 0.02 gm. per kg. for the young animals. The full-grown animals, of which 2 were sick, were about 5 years old. The weights of the animals and the daily yield of milk are given below in Tables II and III.

The increased yield in milk of 5 of the experimental animals is characteristic and, in certain cases, an increase in yield of 1.1 litres per day has been observed; on discontinuing the use of calcium chloride, the yield immediately falls. The young animals showed the benefit of giving calcium chloride; they grew better, their rough hair became smooth and lustrous and they became fatter.

TABLE II. — *Effect of calcium chloride on the live weights of the cattle experimented with.*

		Live weight		Increase (+) or decrease (—) of live weight
		Before using calcium chloride	After using calcium chloride	
Cow No.	1 . . . .	500 kg	544 kg	+ 44 kg

FIGS. — Two sows were experimented on by STADELMANN; one, used as a control, weighed 126 kg.; the other, weighing 195 kg., was given 14 gm. of crystalline  $\text{Ca Cl}_2$  every day; the second animal put on 9 kg. in 22 days, while the first only increased in weight by 5 kg. It should be noticed that 14 gm. is too heavy a dose; a suitable dose would be 4 gm. per 100 kg. live-weight; better results are then obtained. Speaking broadly, the nature of the food given should be considered, on the one hand, as well as the fact that a young animal eats much more in proportion to its weight than a full-grown animal.

CONCLUSION. — Calcium chloride can be very usefully fed to live-stock when the food is lacking in calcareous matter; moreover, when the food only contains this matter in slightly assimilable form, the chloride is then the most suitable salt to give.

## CATTLE

## 188 - Increased Cattle Production on South-Western Ranges of the United States. —

JARDINE, J. T. and HURTH, L. C., in *U. S. Department of Agriculture, Bulletin* No. 588, pp. 1-32. Washington, D. C., November 15, 1917.

This bulletin presents the results of experiments made by the Forest Service on the Jornada Range Reserve, a unit comprising 200 000 acres in New Mexico, with the purpose of working out a system of range management and improvement, practicable for large grazing units, which will build up the depleted areas and ensure the maintenance of the whole range in good condition.

The problem involves : — a) Finding a system of management that will best bring about natural reseeding of the existing forage plants, b) finding new plants suitable for seeding on the ranges of the Southwest ; c) determining the number and distribution of stock-watering places necessary for efficient use of the range, taking into account cost of construction and returns expected ; and d) determining the carrying capacity of the range as a means of preventing its being overstocked. Other and related range problems also have been studied on the Jornada Reserve. One of these has to do with improving the average grade of stock and the average calf crop under range conditions, the possibility of which is generally recognized. Another is how to reduce the losses of stock from lack of feed and water in times of drought and from disease and straying that ordinarily occur in the Southwest.

These studies on the Jornada Reserve are by no means completed ; the results so far secured, however, seemed to have an important enough bearing on the problem of increased meat production, to justify the publication of this progress report which illustrates methods already successfully applied on a practical scale since 1912 when the Reserve was created by Executive order.

The Jornada Range Reserve is located in Dona Ana County N. Mex., in the Rio Grande Valley, about 50 miles north of the Mexican boundary. It is typical of a large territory in the Southwest which, owing to natural and climatic conditions, will probably always be best adapted to the production of live stock on comparatively large holdings.

The eastern portion of the Reserve includes the west slope of the San Andreas Mountains which reach a maximum elevation of about 7 600 feet, and the remainder of the Reserve is a comparatively flat or slightly rolling plain.

The locality is one of the most arid of the Southwest. Records for 55 years at Mesilla Park, about 15 miles southwest of the Reserve, show an average annual precipitation of 8.63 inches, with precipitation for individual years as much as 17 and as little as 3.50 inches. Temperatures as high as 106° F. are common in summer, and the region is subject to almost continuous high winds and, consequently, high evaporation. The soils of the plain are rather coarse to medium textured wind-blown sands, with patches of heavy adobe clay, usually with a rather high percentage of alkali, where water often stands until evaporated. The soils of the mountains and the outwash plains flanking them are coarse sands and gravels.

The vegetation is comparatively thin and made up of drought-resistant,

semidesert species. By far the greater part of the forage, perhaps 80 %, is furnished by perennial grasses, of which the most important are grama grasses.

Black grama (*Bouteloua eriopoda*) is the most important grass of the Reserve. Blue grama grass (*B. gracilis*) and hairy grama grass (*B. hirsuta*) are found only in the mountains and foothills.

Next to the grama grasses in importance are three-awn grasses known locally as "needle grasses" (*Aristida longiseta*, *A. pansa*, and *A. purpurea*); tobosa grass (*Hilaria mutica*).

The drop-seed grasses include several species, the most important being *Sporobolus cryptandrus*, *S. flexuosus*, *S. wrightii*, *S. airoides*, *S. auriculatus*.

The most important species of muhlenbergias are *Muhlenbergia gracillima* and *M. porteri*.

Burro grass (*Scleropogon brevifolius*) and wolftail (*Lycurus phleclides*) are also to be found.

On large areas of the foothills, black brush (*Flourensia ceruna*), creosote bush (*Covillea glutinosa* = *Larrea glutinosa*) and mesquite (*Prosopis glandulosa*) predominate; but black brush and creosote bush are worthless as forage, and the mesquite is of low value.

Stock water for the plains, both on the Reserve and on the adjacent range lands, is pumped from deep wells by windmills and engines or is provided by tanks which catch the flood waters. As a usual thing, there is not enough water for the stock.

EXPERIMENTAL RESULTS SO FAR OBTAINED IN RANGE MANAGEMENT. — *Range Improvement by Natural Revegetation.* Primarily as a result of 1) reducing the number of stock during the main growing season of about four months — July to October — to about half the average number the area will carry for the year, 2) not overstocking during the other eight months, and 3) better distribution of stock watering places, grama grass range on the Jornada Range Reserve has improved in three years at least 50 per cent. as compared with similar adjoining unfenced range grazed all the year. Observations to date indicate that range thus lightly grazed during the main growing season has improved approximately to the same extent as similar range protected from grazing the entire year.

On fenced grama-grass ranges of the Southwest where the stock are carried mainly on range feed throughout the year, light stocking during the growing season is profitable.

It will probably not reduce the total animal-days' feed furnished on a given area during the year, and will reserve feed for the critical period from February to July, or later in case of prolonged drought.

Where the whole of a range unit is made up of grama or similar grass, about one third of the area should probably be reserved for light grazing during the growing season two years in succession. Each third in turn should be given as nearly as practicable this amount of protection. By light grazing is meant grazing by not more than half the average number of stock that the area will carry for the year as a whole.

*Water Development.* — Fairly efficient use of plains and mesa range in the Southwest can be secured where stock do not have to travel more than

2 ½ miles to water. This means one watering place for each 13 200 acres. Such an acreage of grama-grass range will carry about 500 cattle throughout the year if properly managed. When feed is short, a long distance between feed and water tends to increase the loss of stock, to decrease the calf crop, and to retard development of the young animals.

Observations to date appear to justify one permanent watering place for each 500 head of cattle. Where conditions are favorable the construction of tanks to catch flood waters for the purpose of supplementing the permanent watering places will be a paying investment.

They will aid: 1) in getting more green feed for the stock during the year; 2) in more even utilization of the range as a whole; 3) in the protection of feed and range near permanent water; and 4) in reducing the cost of maintenance and operation of wells.

*Carrying Capacity.* — During 1916 the Jornada Reserve as a whole supported one animal, not including unweaned calves, on an average of 41.45 acres. The estimated maximum carrying capacity of the Reserve in its present stage of development is 38.1 acres per head. The estimated carrying capacity of similar unfenced range in its present average condition is at least 50 acres per head.

The range of the plains, where grama grasses form the bulk of the forage, will support stock throughout the year at the average rate of one head to from 20 to 30 acres, depending upon the proportion of the real grama-grass type. This figure is for range in good condition, fairly well supplied with stock water, and which is lightly stocked during the growing season.

The range comprising tobosa-grass flats, along drainage lines, and slopes back to the foothills will support stock throughout the year at the average rate of one head to from 38 to 45 acres, depending upon the percentage of tobosa flats which receive flood water.

¶ The mountain range of the Jornada Range Reserve will support stock at the rate of approximately 60 acres per head in its present stage of development.

*Increase in Calf Crop and Improvement in Grade of Stock.* — From 500 selected cows and 20 bulls, held in pastures away from other stock since August 1915, an 81 per cent. calf crop was branded in 1916.

From the remaining cows of breeding age, amounting to 1 522 head run together in one pasture of 74 714 acres, a 69.2 per cent calf crop was branded. The average calf crop for the Reserve was 72 per cent. A total of approximately 50 pounds of cottonseed cake per head was fed to the 500 cows and 20 bulls of the selected breeding herd on the Reserve.

¶ The work of caring for this herd took half of one man's time. The extra calves in this special herd far more than paid for the extra feed and labour.

*Prevention of Loss.* — The average loss of stock on the Jornada Reserve from June 1 to December 31, 1915, was at the rate of 1.9 per cent. for a year; the average loss in 1916 was 1.5 per cent. The average losses for New Mexico are approximately 10 6 per cent for calves to 12 months of age, 5.6 per cent. for yearlings, and 5.8 per cent for other stock.

The small loss at the Jornada Reserve is attributed to careful systematic vaccination against blackleg, to the reservation of grama grass range for  
[1916]

poor stock during the critical spring months, to feeding the animals a small quantity of cottonseed cake and to prevention of straying.

In order to provide for extra range for the breeding stock in poor years, one third of the stock on a range unit should be steers. It is then possible to reduce or increase the stock according to years without interfering with the breeding stock.

To provide against loss in extremely bad years some kind of roughage to supplement the range forage, for feeding with cottonseed cake or other concentrated feed, would be a decided advantage on southwestern ranges.

Ensilage made from soap weed (*Yucca elata*) has been tried, and the results are promising but not extensive enough to warrant definite conclusions.

Range feed not more than 2  $\frac{1}{2}$  miles from water is a big factor in cutting down loss from starvation, especially where little or no supplemental feeding is done.

**189 - The Awankari Cattle Herd of the Peshawar Agricultural Station in the North-West Frontier Province of India.** — BROWN, W. ROBERTSON, in *The Agricultural Journal of India*, Vol. XII, Part IV, pp. 588-592. Calcutta, October, 1917.

In the autumn of 1916 ten beautiful typical Awankari cows were introduced, from their home in the North Punjab, to the Peshawar Agricultural Station. Awankari cattle, although alien to the North-West Frontier Province, are valued above other breeds by the cultivators, because they are hardy, handy, powerful and fast alike in the cart and in the plough, and handsome in appearance. Their even black and white markings and free bold carriage appeal to breeders; but until these cows arrived at the Agricultural Station there was not a pure-bred female of the breed in the Peshawar district.

*Awankari Herd at the Peshawar Agricultural Station.*

*Cows.*

Name	Age, years	Length	Height	Girth	Shin	Colour	Price	Calfborn	Remarks

Laila .	7	52	41 <sup>3</sup> / <sub>4</sub>	59	6	»	85	1- 5-17	Good milker
Ranai .	8	48	47	62	6	»	65	—	Typical cow
Bull.									
Rustum .	4	60	51	75	7	»	130 (2 years)		Handsome typical bull
Bullocks.									
	6	54	52	68	7	»	140		A beautiful
	6	57	52	6	6 <sup>1</sup> / <sub>2</sub>	»	140		well-matched pair

Four of the cows are by no means poor milkers, so it is hoped that a herd of fair milkers may ultimately be established without sacrificing any of the more important qualities the breed now possesses. The young stock promise to be excellent typical specimens fit for stud, or inclusion in the Station Herd Book. In the table of measurements given below, the cows compare unfavourably with the bull and bullocks in size and "bone" because the calves were originally generously treated, whilst the females received bare sustenance.

A set of 5 photographs is given in the original text.

## SHEEP

190 - **The New Zealand Sheep Returns in 1917 and the Progress of Crossbreeding in New South Wales.** — *The Pastoral Review*, Vol. XXVII, No. 11, pp. 1040-1041 Melbourne, November 16, 1917.

The complete figures of the New Zealand sheep returns just issued, show that there has been an increase of 482 236 over the previous year. The increase for the North Island is 686 329 and the decrease for the South Island 204 093. The New Zealand figures supply much interesting and valuable information because separate totals are given of stud rams, flock rams, wethers, breeding ewes, dry ewes and lambs.

According to these returns there were in the Dominion 10 484 stud rams, 318 766 flock rams, 3 457 000 wethers, 13 260 000 breeding ewes, 1 072 647 dry ewes, and 7 150 516 lambs. There is also shown the number of stud sheep entered in the flock book, and the sheep of a distinctive breed, but not entered in the flock book. Romneys, Lincolns, Border Leicesters, and Southdowns, the favourite crossing breeds, lead the way, but the first-named is far ahead of the rest, there being 117 478 stud and 3 702 641 flock Romneys, as against 40 083 stud and 585 943 flock Lincolns, which come second. Border Leicester studs and flocks number respectively 35 992 and 311 407, Southdowns 26 393 and 50 019, English Leicesters 24 367 and 173 146, Merinos 17 187 and 1 063 491, and Shropshires 4 109 and 22 380. The number of crossbreds and others not otherwise enumerated is 18 395 222.

The figures for New South Wales also throw an interesting light upon the development of crossbreeding. In the 1907-1908 season the percentage of crossbred wool sold in the Sydney market was 3.77 % of the total offerings. It steadily increased to 8.73 % in 1912-1913, and the following year suddenly increased to 11.05 %. From then onwards progress was more rapid and during the 1916-1917 season the wool sold in Sydney was 21.14 % crossbred and 78.86 Merino. Unfortunately, there are no accurate statistics available illustrating this development in the various pastoral districts of each State. It would be interesting to know whether this increase of crossbred wool is the result of an increasing use of sheep on the wheat areas, or whether the crossbred is making a steady encroachment on to what has hitherto been considered pure Merino country. It would also be most useful to know what Longwool breeds are forming the basis of such marked development in crossbreeding. It is well known that the Romney, Lincoln, and Leicester are the predominating British breeds in New South Wales and New Zealand, that are used for crossing with the Merino, but there are no statistics for the Australian States which can be taken as evidence of

the relative part each breed is playing in this increasing production of crossbred wool.

The 25 270 386 sheep of New Zealand belong to 23 380 different owners, giving an average of a little over 1000 sheep per owner. There are no less than 18 255 owners whose flocks do not exceed 5000 and 11 809 of these owner's flocks do not exceed 500. There are only 38 owners with flocks exceeding 20 000. The number of owners has increased during the year by 199. This increase is partly due to new settlers starting flocks, and to a smaller extent to dairy farmers who have been forced, by shortage of labour, to give up cows for sheep.

191 - **The Importance of Hogs for the Meat and Hides Supply.** — FISH, P. A., in the *Journal of the American Veterinary Medical Association*, Vol. LII, No. 3, pp. 245-247. Ithaca, N. Y., December, 1917.

PIGS

It is estimated that at present there are in the United States 4 000 000 hogs less than there were a year ago. Outside of the United States there has been a decrease of 39 525 000 hogs. This number has been exceeded only by sheep. Cattle are not far behind the hogs in their diminishing numbers.

To assist in meeting the great demand for meat the U. S. Department of Agriculture estimates that the number of hogs should be increased 15 per cent. for the entire country. In some states the increase needed is only 5 per cent., in others, as much as 50 per cent. This policy seems completely justified because among the domesticated animals there are none so prolific; none which produce so great a return in so short a time; none in which so wide a variation in diet is possible; none more useful in the variety of products afforded.

Nevertheless, there is one important product of the hog which does not seem to be used at its best advantage, under modern methods of curing ham and bacon, and that is the hide.

The deficiency in leather is becoming serious and pig skin is the only substitute, in large quantities, available for cowhides. The skins of the millions of hogs slaughtered annually could be converted into the finest kind of leather. Such leather is superior to cow hide in resisting surface wear and has been used for years, but in limited quantities, in making the finest saddles and fancy leather goods. It has been tested and found thoroughly practicable and satisfactory for shoes.

It is stated there is a shortage of three million cowhides to meet in the open market. The pigskins would make up this deficiency twice over considering that the presence of the skin is not indispensable in preserving the meat, under the modern methods of curing.

In the supply of meat and leather, the hogs, as quick breeding animals, seem therefore to meet the need. Unfortunately they are susceptible to diseases which annually take a toll of millions from the supply. But the use of anti-hog cholera serum is to day far beyond the experimental stage. It has checked the disease in the infected herds and immunized healthy hogs exposed to the disease; therefore, with a greater educational interest

and with proper cooperation on the part of the producers and of the veterinarians, it seems only a question of time and organization to avert the menace of hog cholera.

## BEE KEEPING

192 - "Le Sughere" Hive with Cork Frames. — PECCHINI, GIOVANNI, in *L'Apicoltura Italiana*, Year XIII, No. 12, pp. 188-189. Ancona, December, 1917.

In order to protect the bees against heat, cold and especially sudden changes of temperature in spring, the author constructed a hive with cork frames. All models may be built on this system.

193 - The Cotton Plant as a Honey-Yielding Plant. — *Chacaras e Quintas*, Vol. XVI, No. 4, p. 299. São Paulo, October 15, 1917.

It is not generally known that the cotton plant is one of the best honey-yielding plants. The honey obtained from it is very clear and, when it is completely ripe, very sweet. It granulates easily and, when solid, is of a very fine, almost white grain.

## SERICULTURE

194 - Comparative Research on the Value of the Electrical and Chemical Treatments of Silkworm Eggs (1). — ACQUA, C., in *Informazioni Seriche*, Year IV, No. 21, pp. 493-494. Rome, Nov. 5, 1917.

During the spring and autumn of 1917 the author carried out 38 series of experimental rearings, in which he reared, under the same environmental and food conditions, for each series, lots of eggs treated by electricity or hydrochloric acid for a varying duration of time. The races used were native yellow, Chinese white and gold at their first crossing and the product of some of these crossings.

For the hydrochloric acid treatment one of the methods most generally acknowledged to be favourable was used. It consists in treating native yellow eggs with fuming hydrochloric acid diluted in  $\frac{1}{10}$  of water; during 15 minutes, and the Chinese eggs for a few minutes less.

For the electric treatment, electrification of the eggs contained in bags between the two electrodes was sometimes used, but more often "electric rain". The author has so modified this method that the eggs may be subjected directly to the "electric rain", without being placed in silk bags as was done hitherto. By this method, which will be described in a later paper, it is possible to avoid, partly at least, the drawback resulting from a difference in treatment which sometimes occurs with more or less powerful apparatuses during more or less dry periods.

Of the 38 series, 10 gave results slightly favourable to the electric treatment, at least some of the lots giving better results than those treated with hydrochloric acid; 28 gave results distinctly unfavourable to this treatment, for all the worms died before reaching maturity, whereas those from eggs treated with hydrochloric acid always proved much more resistant, and often gave good results. The most prolonged electric treatment appears the least favourable. From these experiments it was concluded that *the electric treatment is clearly inferior to the hydrochloric acid treatment, which, being also the more simple, should be preferred.*

(1) See R. Jan, 1918, No 76 (Ed.)

The loss of weight of the eggs treated with electricity or acid for each day between the treatment and hatching was also studied. The results showed that, within the limits of complete hatching, the loss of weight is in direct proportion to the duration of the treatment, but prolonged treatment often decreases it. The progress of this phenomenon will be shown by tables in the author's coming paper.

Finally it is shown that, when hatching is brought about prematurely by hydrochloric acid, the eggs, though they remain strong, often give bad results on account of the excessive summer heat. This is easily explained if it is considered that annual breeds, which already suffer in hot springs, bear the summer with difficulty.

The special treatment cannot give new vigour to the breed; it must suffice that it does not weaken it appreciably. These methods, like that of prolonged estivation, give good results for breeding at moderate temperatures, but at very hot temperatures, breeds already adapted to these conditions must be used. Crossing with bivoltines should give the desired result. They have already been thoroughly studied with respect to their products and especially the profit they give, and attempts should now be made to use them practically, by solving some of the difficulties which arise.

**195 - Selection by Phototaxy of Newly-Hatched Silkworm Larvae with Regard to their Strength.** — ACQUA, C., in *Rendiconti dell'Istituto bacologico della R. Scuola superiore di Agricoltura in Portici*, Vol. II, pp. 51-77. Portici, 1917.

In his preceding work (1) the author showed that silkworm larvae, on hatching, move towards the light (positive phototaxy), whereas, at later stages, they tend to avoid it (negative phototaxy), and that the larvae showing the most active phototaxy are also the most resistant to "flacherie". In his present work the author has restudied phototaxy on a larger scale, making numerous experiments (33) with many breeds (native yellow, Chinese white, Chinese gold, Chinese bi-yellow) reared in spring, summer or autumn. In order to separate the larvae showing a greater phototactic activity from those showing a lesser, he used an incubator with double walls, the space being filled with water, long enough to hold 8 small frames about 1 foot wide and 3  $\frac{1}{4}$  feet long, with two doors, the back one of wood, the front one of ground glass. A few hours after hatching, there are placed rapidly on different parts of the frames, narrow strips of mulberry leaves, or, better still, on the cloth forming the bottom of the frame, sheets of paper, whose edges overlap, like tiles of a roof. When collecting the mulberry leaves from the different parts, or the sheets of paper, the larvae which have moved most rapidly towards the light are separated from those which have moved more slowly, or not at all. The results of these 33 experiments confirm in every way those of the two preceding studies, and leave no doubt that larvae which show the greatest phototactic activity are also the strongest, grow the most rapidly, are the most resistant to disease and produce the heaviest cocoons.

(1) See R. March, 1916, No. 328; and R. June, 1917, No. 572. (Ed.)

The use of this method of selection in practice has give only negative results in attempts to test the strength of the eggs, at the beginning of spring before their distribution for ordinary rearing. This is because the phototactic reaction varies with the different breeds independently of their strength. This method is also unadapted to ordinary rearing by putting in a room, dimly lit on one side only, a number of eggs exceeding that to be reared and rejecting the slowest-moving larvae, because the number of larvae reacting strongly to light is usually small; the bulk move more or less in a continuous line so that, considering the difference between one breed and another, the rearer has no positive indication of where he must stop. On the other hand, selection by phototaxy may be used as a means of improving breeding races in combination with the method now followed of selecting the silk-worms which live longest.

196 - Studies on the Process of Digestion in Silkworm Larvae. — ACQUA, C, in *Rendiconti dell'Istituto biologico della R. Scuola Superiore di Agricoltura in Portici*, Vol. I, pp. 3-44 and Vol. II, pp. 31-50. Portici, 1916-1917.

By: a) the microscopic examination of microtome sections, embedded in paraffin wax, of various parts of the intestine together with their contents; b) the extraction of the intestinal juice of fasting and non-fasting larvae; c) a study *in vitro* of the properties of this juice, the author was able to ascertain:

1) that the cytoplasmatic substances of mulberry leaves which are expelled from their cells by the rupture of their membranes during mastication, disappear gradually in proportion as the posterior part of the intestinal tube is approached, whereas the cells which remain intact appear to pass through the tube unchanged;

2) the starch granules show no trace of change or corrosion;

3) in the intestinal juice there are one or more proteolytic diastases, similar in character to trypsin, and which, among other properties, have that of digesting coagulated ovalbumen, but it was not possible to ascertain the existence of an amylolytic ferment capable of acting on the starch (contrary to the general opinion that the starch may be utilised) or of lipolytic ferments capable of digesting the fats.

In a second study the author has re-tested the results of his first work by undertaking new research: — a) on the proteolytic ferments in fasting larvae and in larvae which have taken a normal amount of food; b) on the eventual occurrence of amylolytic ferments under the above conditions; c) the possible action of the salivary glands. The presence of invertases was carefully investigated. All these studies, as well as the first ones, were confined to the native yellow breed. The results again confirm the low enzyme content of the intestinal juice of the silkworm, in which the author noted a) a low capacity for inverting cane sugar; b) an energetic proteolytic ferment acting in an alkaline medium (such as trypsin) on the soluble, coagulated ovalbumen, on the fibrin of the blood, on the vegetable proteins (zein). It may be concluded that the silkworm digests food principally, or even exclusively, by means of one or more proteolytic zymases, and can then complete its nutrition by absorbing the soluble carbohydrates (sugars) of the

leaf digested. It has been proved that neither the presence of foodstuffs in the intestinal tube, nor the olfactory stimulant, have even the slightest influence on the secretion of these enzymes. It has been proved beyond all doubt that the starch passes unchanged through the intestinal canal of the silkworm. The eventual action of lipolytic ferments calls for further study.

If the reactions which take place in the digestive canal of the silkworm are very limited from a qualitative point of view of the substances contained in the mulberry leaf, the same may be said of the quantitative point of view, for the silkworm only utilises the substances expelled from the vegetable cells as a result of their rupture during mastication, whereas it appears that no action can take place within the cells, perhaps because of the difficulty the enzymes have to penetrate their walls. Nevertheless, the author states in his second study that, in the longitudinal sections of the middle of newly-hatched larvae, fed at the beginning of spring on very young and very tender leaves, digestion was seen to occur, during the passage through the digestive tube, also within the cells. In newly-hatched larvae the small intestine is much more extended than at the later ages in proportion to the other parts; in the above case a beginning of digestion was also noted near the front intestine.

Consequently, the custom of giving newly-born larvae very tender leaves does not only facilitate digestion, but also facilitates the penetration of the enzymes through the cellular membranes, which, in this case, are very thin and easily penetrated.

Finally, the author made an experimental test with tubes of MERT (coagulated ovalbumen) on the action of the proteolytic zymases of healthy larvae and of those predisposed to "flacherie". No difference was noticed, so that it would appear that the disorders noticed in the intestinal juice of larvae suffering from "flacherie" do not precede the disease, but are a result of it. The author is continuing the study of this question.

197 - On Natural Parthenogenesis in Various Breeds and Varieties of *Bombyx mori* (1). — LÉCAILLON, A., in *Comptes Rendus des Séances de l'Académie des Sciences*, Vol. CLXV, No. 20, pp. 799-801. Paris, December 3, 1917.

This paper gives the results of experiments carried out to ascertain if the aptitude for natural parthenogenesis in the silkworm varies with different breeds or varieties.

The material used was: — 1) 3 lots, each of about 400 unfertilised eggs, laid by univoltine silkworms giving straw coloured cocoons; 2) 10 lots of unfertilised eggs from accidental bivoltines; 3) 5 lots of unfertilised eggs from a Chinese polyvoltine breed.

The results obtained led to the conclusion that there is a real aptitude for parthenogenesis in all breeds of *Bombyx mori*, but there are many variations in the degree of development of this aptitude. The parthenogenetic transformations which take place in the egg may stop at a stage which appears to be extremely early, or continue till a larva is produced capable of living and developing just as well as those from fertilised eggs.

198 - Note on Sericulture in Madagascar (1). — FAUCHÈRE in *Comptes Rendus des Séances de l'Académie des Sciences*, Vol. CLXV, No. 20, pp. 676-677. Paris, November 12, 1917.

The author, being entrusted with the reorganisation of the sericultural service in central Madagascar, was able to make new observations which he reports in the present note.

The races of *Sericaria mori* introduced into Madagascar come from the South of Europe and were all monovoltine. After two years, by adaptation to the climatic conditions in the centre of the island, they became polyvoltine, breeding six generations a year. The cocoons are identical with those of the same races which have remained monovoltine, and their silk is of first quality. The eggs hatch regularly 12 or 13 days after they are laid, without its being necessary to subject them to the action of cold which, indeed, appears to be detrimental to them.

As in Europe, diseases are to be feared, especially pebrine; this disease is aggravated in tropical countries by the fact that the generations succeed each other throughout the year without interruption, and also on account of the negligence of the native breeders. The author observed that pebrine is less easily transmitted than is generally believed. He, therefore, made breeding from separated families a strict rule for the production of eggs at the Sericultural Station of Nanisana, near Tananarive. He perfected the method of cellular egg production as practised in Europe: the couples are placed on sheets of paper placed on strips of wood, then covered with a sort of tin funnel to prevent the eggs from mixing and, also, to obtain a large number of eggs in a limited space.

These remarks only apply to *Sericaria mori*, and not to *Borocera madagascariensis*, a native species of very different habits giving a coarse silk.

## FARM ENGINEERING.

### AGRICULTURAL MACHINERY AND IMPLEMENTS

199. — **Tractor Trials in Scotland in 1917.** — *The North British Agriculturalist*, Vol. LXIX, No. 49, p. 740. Edinburgh, December 6, 1916.

The official report of the Reporting Committee of the Highland Agricultural Society of Scotland on the tractor trials held at Edinburgh, Glasgow and Perth, in October, 1917, gives the following classification of the 29 machines that took part in the trials:

1) *Wheels*: 15 ran on 4 wheels; 6 on 3 wheels; 4 ran on caterpillars and 4 were single-unit machines.

2) *Driving*: 18 tractors were handled by 2 men, while 18 were one-man outfits.

3) *Fuel*: 25 were operated by paraffin; 3 by petrol and 1 by steam.

4) *Weight*: 2 weighed over 80 cwt.; 3 over 60 cwt.; 6 over 50 cwt., 7 over 40 cwt.; 3 over 30 cwt.; 8 less than 30 cwt.

(1) See R. August, 1916, No. 891. (Ed.)

The report does not class the tractors in order of merit, but it gives observations that will be of use to both farmers and engineers; these observations are given below.

**WEIGHT.** — Light machines, suitably provided with spuds, grip the ground and perform the work better than the heavier machines. Every drawback, such as slipping in soft land and inability to climb gradients, was aggravated by increase of weight above a certain limit. A heavy tractor is, moreover, at a disadvantage for the lighter forms of cultivation, such as grubbing, cultivating, seeding and harrowing and also for harvesting. The light tractor is quite suitable for all the farm operations, including driving a threshing-mill and other farm machinery. The only class of work for which the light tractor does not appear to be suited is road haulage. The conclusion was reached that, to suit conditions in Scotland, an efficient land tractor need not exceed 30 cwt. in weight.

**HORSE-POWER.** — For various reasons such as inexperienced drivers, loss of power due to soft ground and clogging of the wheels and moving parts with mud, etc., the tractor should have a minimum of 20 b. h.-p., so that it can haul a 2-furrow plough under the worst conditions, and a 3-furrow plough under ordinary conditions; it should also be capable of driving a 4 ft. 6 in. threshing-mill.

**CATERPILLAR VERSUS WHEELS.** — While this arrangement distributes the actual dead weight and thus reduces the intensity of pressure on the land, it appears certain that there must be excessive wear and tear on the caterpillar. As far as the Committee could observe the caterpillar has no advantage as regards gripping power over the best types of wheel machines.

**SPIKES, BARS AND SPUDS.** — A stout spud 3 in. to 4 in. in width and 4 to 5 in. in length appears to be more satisfactory than spikes or bars, especially when these spuds are so arranged in relation to the circumference of the wheel, that the full gripping power of one spud is always in operation.

**ACCESSIBILITY AND PROTECTION.** — The report notes the importance given to rendering the vital parts of the machinery more accessible and also to providing protection against the weather.

**BRAKES.** — For transport purposes, all tractors should be provided with adequate brakes.

**RELIABILITY AND DURABILITY.** — Seeing that only one machine failed to complete the 6 days' work, it seems that a fair degree of reliability has been attained. In spite of the bad state of the ground, the tractors overcame all the difficulties. Two defects were noted as tending to impair durability. These are the exposed gear drives on some of the wheel tractors, which fill with mud and grit, and the already mentioned excessive wear of the caterpillar arrangement.

**SPRING AND OTHER CONNECTIONS.** — The Committee are of the opinion that the drawbar should be provided with some spring appliance, which would relieve the strain on the plough in the case of encountering minor obstacles. With this might be incorporated a release device, which would completely detach the plough under the strain of a heavy shock. This attachment should be an integral part of the tractor and not merely a ca-

sual device inserted in the draft connections. Provision should also be made for altering the point of attachment of the plough to the tractor in a vertical direction. This is important as different implements require different heights of attachment.

**SPEEDS.** — It is suggested that speeds of  $2\frac{1}{2}$  and 4 miles per hour should meet the requirement of a tractor for use on the land.

**FUELS.** — Although no tests of fuel consumption could be carried out, it was found that the carburettors of many of the tractors were not capable of thoroughly and completely vaporising paraffin, and that the combustion was, in consequence, defective in many cases. Under normal conditions, it may be found that petrol is more satisfactory to use than paraffin.

**PLOUGHS.** — They should be made so as to be easily adjusted to varying widths so as to suit the depths and the class of work. Automatic lifting should be provided. They should be provided with a device for regulating the width of the leading furrow.

The Committee further suggest that :

1) If the last unit of the plough could be made so that it could be thrown out of action by being raised with a lever or otherwise, then 2 furrows could be ploughed on an up gradient and 3 on a down.

2) The introduction of a one-way plough would obviate the necessity of having feelers and finishes, most of which, under present circumstances, must be performed with horses.

**HANDLING.** — The handling of the tractors did not appear to present any great difficulties. The single unit machine has the advantage that the implement operation was directly under the observation of the driver. The light tractors and single-unit machines were able to turn more quickly at the headlands.

**PRICE** — The question of price is a difficult one under the present abnormal conditions. Manufacturers should, however, aim at putting a tractor on the market at a price not exceeding £ 300.

200 — **Ploughing and Harrowing with a Tractor.** — RINGELMANN, MAX, in the *Journal d'Agriculture Pratique*, Year LXXXI, Vol CXXXI, New Series, Vol XXX, No 25, pp. 487-489, figs 3 Paris, December 17, 1917.

Land ploughed in autumn before sowing and especially spring-ploughed land, should be harrowed as soon as possible. With a tractor, ploughing and harrowing can be carried out simultaneously, by using a simple attachment to the plough.

In the appended figure, giving a diagram of a 3-furrow plough, *a, b, c*, moving in the direction *f*, it will be seen that the harrow *H* can be attached by a chain *t* to a suitable point of a cross bar *dd'*, fixed to the beams *a'* and *b'*. The cross-bar, a 60 mm. beam of wood or iron, is fixed to the beams *a'* and *b'* by bands, and strengthened by a brace-rod *c*. The hook of the chain engages in one of the holes of the cross-bar *d'*, which regulates the width. The position of the chain *t* should be such that the harrow *H* does not work the last earth turned by the plough *c*; the harrow works on the bands *a* and *b*, then the last furrows turned previously; in this way, no earth falls

in the furrow opened by the plough *c*, and thus no interference is caused with the automatic guidance of the tractor.

The harrow should cover a greater width than the plough. After trials with the 20 HP Titan and 20 HP Mogul tractors, excellent results were obtained with the grouping used by the "COMPAGNIE INTERNATIONALE DE MACHINES AGRICOLES"; the 30-tooth harrow, 61 inches wide, was attached to a 3-furrow plough covering 35 inches. According to the depth to which the harrow teeth penetrated, the average extra traction required varied from 374 to 572 lb. The use of a harrow with adjustable teeth, that can be lifted with a lever at the headland, is advisable. The drag-harrow may be replaced by an "Acme" or a disc-harrow. If the tractor is used for harrowing alone, the width of work may be increased by hitching several harrows to a drawbar. In this case, the tractor should not press heavily on the soil, causing packing, and uneven harrowing, with a consequent bad effect on the crop. In the lack of further data on this point, the author thinks that the weight should not be greater than that of 25 kg. per cm. width of tyre.

A harrow frame with seat, joined to the draw-bar, is described which is mostly used in the United States. In 1886 the author had tried such a frame with a seat, built by F. PUZENAT.

Method of coupling a harrow to a 3-furrow plough.

201 - **Harvesting with a Tractor.** — RINGELMANN, MAX.: I. *Journal d'Agriculture pratique*, Year LXXXI, New Series, Vol. XXX, No. 19, pp. 366-368, figs. 3. Paris, Sept. 20, 1917, — II. *Bulletin de la Société d'Encouragement pour l'Industrie Nationale* Year CLVI, Vol. CXXVIII, No. 5, pp. 314-318, figs. 4. Paris, Sept.-Oct., 1917.

I. — Information regarding harvesting with a tractor carried out in 1917 by the "Syndicat de culture mécanique de Sencenac-Puy de Fourche (Dordogne, France), and communicated to the author by M. BIRABEU, of Laborie-Fricard, a managing director of the company.

A 25 HP. Case tractor was used to draw 2 binders with 59 in. cutter-bars. It was estimated that the tractor could have towed 3 binders on flat ground.

The appended figure shows how the machines were attached: the trac-

tor  $T$  moves in the direction shown by the arrow  $f$ , towing 2 binders  $M$  and  $M'$ ;  $R$  is the crop to be cut.  $M$  is attached to the extreme right of the tractor by a small shaft  $a$ , 59 in. long, to which is fixed a towing rod  $b$  receiving a short oblique wooden pole,  $c$ , 79 in. long, whose far end is joined to the base of the shaft  $d$  of the binder  $M'$ . The small shaft  $d$  is supported by a roller  $r$  and forms with  $c$  an angle held by a rod  $e$  acting as a stay. The right-hand driving wheel of the tractor passes at 10 in. distance from the edge  $y$  of the crop  $R$ . The cutter-bar of  $M$  works on its full length, about 55 in., while that of  $M'$  only cuts a width of 49 in. The width cut in each turn (distance between  $y$  and  $y'$ ) is about 102 in.

Plan for coupling 2 binders  
to a tractor.

II. The tractor with the 2 binders, working under the conditions described, burns, on very undulating land, 12.10 gallons of gasoline in 16 hours to cut 15 to 17 acres; the whole assemblage worked for 2 consecutive weeks without stoppage.

With 2 binders attached, the corners of the field should be rounded off on a large area; thus, several machines coupled together would only be suitable for work on large areas. When the width of crop to be cut is about 100 ft., it is more economical to cut only on the 2 long sides, leaving enough space for turning at the ends, removing sheaves that impede the passage.

The author reduces these figures to the rate per hour, using his previous observations made on the 25 HP. Case tractor.

The weight of fuel burned per acre should vary about 4.6 lb., which is not excessive.

Working speed	{ per second . . . . .	35.43 in.
	» hour . . . . .	3546 yd.
Width of cut . . . . .		102 in.
Surface cut . . . . .	{ per second . . . . .	25.29 sq. ft.
	» hour . . . . .	6696 sq. ft.
Actual time worked per hour . . . . .		46 min.
Fuel burned . . . . .	{ per hour . . . . .	1.10 galls.
	» acre . . . . .	0.7 galls.

202 - **The Maillet Field and Vineyard Tilling Machine.** — FRÉMIER, VICTOR, in *Le Génie Rural*, Year X, No. 74, New Series, No. 14, p. 11, fig. 4. Paris, 1917.

M. MAILLET has changed his single unit tilling machine (1) into an agricultural motor with 2 driving wheels; in addition, he has modified the

(1) See R. Oct., 1916, No. 1111. (Ed.)

vineyard-tilling apparatus. Two types are made, one of 12-15 HP., the other of 20-25 HP.

The small model is more specially designed for use with vines planted 63 to 87 in. apart. Its total length is 102 in., its width 47 in., its height 55 in. The frame, which supports the machinery (enclosed in special gear-boxes), is on 4 wheels, 2 front ones for steering, 2 rear ones for driving. The engine is in front. The gear-box is in the centre and includes 3 super-imposed axles; the central one works the driving wheels through the upper axle. The lower axle drives the tilling apparatus. Three speeds and a reverse are provided for the machine, and 2 or 3 speeds for the tilling apparatus.

This tractor can serve many purposes as it can be used as a tractor for all the ordinary farm vehicles and implements. The appended figure shows the MAILLET tractor working between 2 rows of vines.

MAILLET Field and Vineyard Tilling Machine.

203 - The "Kardell 4 in 1" Tractor. — *The Implement and Machinery Review*, Vol. XXXXIII, No. 512, p. 838, fig. 1. London, December 1, 1917.

A new tractor built by the KARDELL TRACTOR & TRUCK Co., St. Louis, U. S., A., which can perform 4 different operations: — ploughing, tractor work, motor carting and generating farm power (1).

(1) *The Farm Implement News*, Vol. XXXVIII, No. 6, Chicago, Feb. 8, 1917, gives the following additional information: — weight, 5300 lbs; 4 cylinder engine, working at 900 revs.; 35 HP stated, and 16 HP at draw-bar; fuel, petrol or paraffin; driving wheels; diameter, 60 in.; tyre width, 12 in.; price, \$ 1250. (Ed.)

It is claimed that the tractor meets all the requirements of an average farm of 100 to 500 acres, both for its simplicity of construction and strength and for the multifarious duties it can perform.

As shown in the annexed figure, the 2 driving wheels are of a new type, carrying a webbed tread, tending rather to loosen than pack the soil, and at the same time preventing slipping.

The ploughs are carried under the main frame, an arrangement which is said to reduce the draft by 33.3 per cent. Three 14-in ploughs are attached to an adjustable spring draw-bar, which automatically stops the ploughing when a rock or stump is encountered. The ploughs are so regulated that they individually follow the contour of the ground, and secure an even depth under all conditions. It is claimed that from 12 to 15 acres a day can be ploughed. The machine can be driven in either direction with ease. The ploughs can be easily removed, and the tractor used as a tractor or truck. A 20-in pulley is provided for driving stationary machinery.

"Kardell 4 in 1" Tractor.

204 - **The "Eros" Tractor Plough.** — *The Implement and Machinery Review*, Vol XLIII No. 512, p. 831, 1 fig. London, December, 1, 1916

The "Eros", manufactured by J. M. B. COLLINS, of Bacton, Norfolk, England, is a self-lift 3-furrow plough, which can be easily converted into a 2-furrow implement.

One of its most noteworthy features is a patent automatic lifting device, which utilises the forward movement of the tractor, instead of using springs. By merely pulling a cord, a small catch is released and the lifting gear automatically comes into action, lifting the plough out of the furrow when at the headland. By turning a small handle the depth of ploughing can be regulated while the plough is at work. It turns a furrow  $9\frac{1}{2}$  in wide and from 8 to 9 in. deep.

[~~insert~~]

The frame is of flat steel, strongly riveted to withstand the strain of tractor work. The total weight of the plough is about 6 cwt.

205 - **The W. A. Wood Motor-driven Binder.** — *The Implement and Machinery Review*, Vol. XLIII, No. 512, pp. 835-836, figs. 3. London, Dec. 1, 1907.

Fig. I. — The W. A. Wood binder with a Wood motor mounted in the rear.

In the United States, motor-driven binders are more freely used than in England. During the 1917 season, binders so equipped did excellent work in Scotland. Fig. I shows a WALTER A. WOOD binder equipped with a Wood petrol engine.

Owing to the engine, the crop is cut more easily, especially in the case of tangled crops; the draught is also lightened, for only 2 horses are required instead of 4; moreover, the work is performed in  $\frac{2}{3}$  of the time required for an ordinary binder.

Mr. J. FERRIER, of Wick, using this machine, cut 97 acres of oat and barley in 100 hours, using only 32 gallons of petrol. Fig. 2 shows the 4 H. P. WOOD engine, which can be fixed on the rear of the binder. The engine can also be used to drive any binder, potato digger

Fig. II. — WOOD motor.

or manure spreader. When mounted on a special base, it can be used for running chaff cutters, mills, circular saws, pumps, etc.

206 - **The "Balbo-Bertone" Motor Rice-Harvester.** — TARCHETTI, A., in *Il Giornale di Riscoltura*, Year VII, No. 19-20, pp. 243-247, 2 fig. Vercelli, October 15-30, 1917.

The BALBO-BERTONE side-delivery reaper is an ordinary ADRIANCE machine of which the rakes and the knife-bar are worked by an 8 HP. Felix benzol-burning engine, of Swiss make.

The machine is easily drawn by a pair of horses or oxen, the presence of the engine permitting the ordinary driving wheel of the harvester to be replaced by a lighter wheel of wood (diameter 33 in., tyre 6 in. wide and 4 in. thick) which only carries the weight. In damp and soft soils, a sledge or skate supports the machine when the tyre sinks in the ground. This sledge or skate is 6 ft. 6 in long and placed near the wheel, nearly at the centre of gravity of the machine, so that it will slip along over the mud. Being attached almost rigidly to the beam, the skate can easily pass over dikes and ditches.

The sledge or skate, made of hollow sheet-iron, 6 in. wide, is suspended from the axle by two buffer-springs to deaden shocks against the ground. It also serves as a water-tank for the engine, an ingenious arrangement that saves space and lowers the centre of gravity, which makes the machine more stable and gives rapid cooling against the damp soil of the rice-field.

At the other end of the machine, under the knife-platform is another small spring-mounted skid, near the wheel carrying the platform, the height of which can be easily adjusted according to the height of the cut.

The knife-blade is 59 in. long ; there are 4 rakes, which can work together or in part as beaters. The engine has 1 cylinder and moves the knife-bar to and fro about 250 times a minute.

Without the driver the total weight of machine with the tank full is about 1320 lbs., while the ordinary ADRIANCE No. 6 harvester weighs 940 lbs. The BALBO-BERTONE harvester is 10 ft. 6 in. wide when working and 62 in. when folded up for moving on the road. Its pre-war price was £ 100.

Trials with this machine have been carried out in both a transplanted and an ordinary rice field. It was drawn by 2 oxen lead by a driver ; a mechanic, attending to the engine and the machine, was seated. Except for the unexpected breakage of a gear during the last hour of the experiment, the harvester worked regularly, cutting cleanly, completely and evenly ; the sledge worked very well, the rakes were efficient and the work was not too heavy for the oxen. Before using the harvester, an opening of about a yard should be cut in the rice with a scythe to allow for turning. With the oxen walking at 31.49 in. per second, and the width of cut being 51 in., some 4 425 sq. yds. may be harvested per hour, about 1.5 to 1.8 lb. of benzol being consumed.

207 - **The Use of Wind Engines for Irrigating Semiarid Soils in the Western United States.** — FULLER, in *U. S. Department of Agriculture, Farmers' Bulletin* 866, pp. 38, figs. 11, tables 8, bibliography of 32 Bulletins concerning Irrigation. Washington, 1917.

This bulletin is a new and revised edition of bulletin 394, published in 1910 by the U. S. Department of Agriculture, with the object of showing

how to irrigate small tracts of land cultivated without irrigation by means of wind engines. Information is given as to: — sources of water; boring hydraulic wells; power required to lift water; friction of water in pipes; method for calculating the dimensions of the wind engine to be bought.

To choose such an engine, a Meteorological Bureau should be consulted as to the wind velocity over a considerable period of time. The velocity of the wind is neither constant nor regular, and may vary from 10 to 25 miles per hour in a few minutes.

Ordinary methods for ascertaining the velocity of the wind do not take these fluctuations into account, usually only indicating the average velocity. In choosing a wind engine and pump, the average velocity per hour should be neglected, attention being paid to the time during which the wind attains certain velocities per hour.

Attention should be paid to: — 1) the provision of efficient lubrication; 2) easy renewal of worn parts; 3) strong and accurate construction of the engine and its parts; 4) the reputation of the engine under consideration. Useful information is given regarding the tower, its bracing, anchoring, and construction as well as the care of the wind engine. In 2 tables, applying particularly to Kansas, Colorado, and Nebraska, the author has summarised information obtained by observing and inspecting numerous wind engines, relating to: 1) the area to be irrigated; 2) the crop grown; 3) the number of trees planted; 4) the dimensions of the wind engine; 5) the capacity of reservoirs, the construction and design of which are considered in detail. Circular tanks are the most easy to build, and have fewer disadvantages. A table gives the cost of constructing circular reservoirs of suitable dimensions and capacity for the land to be irrigated.

208 - **The Marcel Landrin Non-Slip Wheel.** — RINGELMANN, MAX, in the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale*, Year CXI, Vol. CXXVIII, No. 5, p. 311-212, figs. 2. Paris, September-October, 1917.

The driving wheels of the MARCEL LANDRIN winch tractor (1) are of the type called "non-slip", the strakes of which, placed obliquely to the spokes, pass through openings in the tyres of the driving wheels. The strakes turn round an eccentric on the axle of the wheels and, according to the position of the eccentric, the strakes protrude at the lower part of the wheel to penetrate in the soil when the machine is working in the field as a tractor, or else protrude on the upper part when the machine is travelling on the road.

209 - **Industrial Alcohol in South Africa.** — *The South African Journal of Industries*, Vol. I, No. 1, pp. 46-48. Pretoria, September, 1917.

The question of producing alcohol as a substitute for petrol as a motor fuel has long engaged the attention of the South African trade. For this purpose many products capable of yielding alcohol were examined — maize,

(1) See *B.* 1914, No. 557. — The *Notes de Culture Mécanique* by Dr. CHAUVÉAU (Paris, Librairie Baillière, 1917) gives the following data as regards this tractor: — Weight 11 000 lbs; 4 cylinder engine of 140 mm. bore and 150 mm. stroke, running at 800 revolutions per minute; 45 HP.; fuel: petrol, alcohol, or paraffin; dimensions: 15 ft. 9 in. X 7 ft. 4 in. X 6 ft. 1 in.; 2 front wheels and 2 driving wheels. (Ed.)

potatoes, prickly pear and cane sugar molasses — but, except in the case of the latter, no definite results have been obtained. In the molasses of the Natal sugar plantations the Union has a source of supply capable of producing an inexpensive alcohol. Up to the present, production on a commercial scale was impossible, owing to the 2 s. per gallon duty. In order to encourage the production of an alcohol to be used as fuel, the Union Government removed this duty on the condition that a satisfactory denaturant be found.

The law demands that 100 volumes of such alcohol shall contain not less than 2 volumes of wood naphtha, and at least  $\frac{1}{2}$  volume of pyridine bases; if the alcohol be mixed with ether, then 1 volume of wood naphtha or benzine shall suffice for every 10 volumes of ether present.

The alcohol shall be coloured blue, green, or violet, with a stable colouring matter. The intensity of the colouration which will be accepted as sufficient is not less than that of a 5 % solution of crystallised copper sulphate.

## RURAL ECONOMICS.

211 - Value to Farm Families in the United States of Food, Fuel and Use of House. — FUNCK, W. C., in *U. S. Department of Agriculture, Bulletin No. 410* (Office of Farm Management), pp. 1-36. Washington, D. C., November, 1917.

The scope of this survey was to determine the value of those things which the farm furnishes to the farm family without money cost, namely the use of a house, food and fuel. The data were secured from nearly 1000 families, representing widely separated sections in 14 States. Figures were gathered covering the value of all food, fuel and shelter, itemized to show what part was bought and what part was furnished by the farm. Data also were collected bearing on the value of household labour on the farm.

Following is a brief abstract of the more significant averages established by this inquiry. The figures given are based on reports from 950 families, averaging 4.8 persons per family.

*Annual value of food, fuel, and use of house : —*

Average per family, \$ 642	Furnished by farm. . . \$ 424		(66 per cent.)
	Bought . . . . .		218 (34 per cent.)

*Annual value of food : —*

Average per family, \$ 448	Animal products	58 per cent.	From farm 58 % Bought . . 42 %
	Groceries . . .	25 " "	
	Vegetables. . .	11 " "	
	Fruits. . . . .	6 " "	

*Annual value of fuel : —*

Average per family, \$ 62	Wood (9.4 cords). .	\$36.30	From farm 54 % Bought . . 46 %
	Coal (2.6 tons). . .	17.85	
	Oil (55 gallons). . .	6.33	

*Annual value of use of house : —*

Average per family, \$ 132.

*Annual value of housework : —*

Average per family, \$ 228	Furnished by family \$ 217 (95 %)	
	Hired . . . . .	

It was found that the average annual value of meats (other than poultry) consumed per family was \$ 107.25 ; of poultry products, \$ 55.40 ; and of dairy products \$ 98.36. (The quantity of dairy products consumed was equivalent to 2 640 quarts of milk).

Meats constitute the most important group of foods. As it increases relative to the other groups the total value of food consumed per family increases.

Those families having a relatively greater consumption of either gro-

ceries, vegetables, or dairy products use relatively less meats, and their total consumption of food is less in value.

Families living on their own farms reported higher consumption of food and a larger proportion of food derived directly from the farm than did those living on rented farms. The average quantity of fruit canned annually per family was 122 quarts; of vegetables 32 quarts. The cost of board (as of hired hands) in food, fuel and house work, was shown to be \$ 129 per year. Thirty-one per cent of this represents cash outlay.

The survey includes the following counties and States: Oxford, Me., Lamoille, Vt., Otsego, N. Y., Bucks, Pa., Gloucester, N. J., Gaston, N. C., Troup, Ga., Mc Lennan, Tex., Champaign, Ohio, Jefferson, Wis., Montgomery, Iowa, Cloud, Kans., Cass, N. Dak., Santa Clara, Cal.

## AGRICULTURAL INDUSTRIES.

212 - **The Composition of the Fixed Acidity of Sound and Diseased Wines.** — LABORDE, J., in *Comptes Rendus des Séances de l'Académie des Sciences*, Vol. CLXV, No. 25, pp. 1017-1020. Paris, December 27, 1917.

The fixed acidity of wines is the difference between the total acidity and the volatile acidity. It is of interest to know the proportions of the various fixed acids in the results obtained by the determination of the acids as a whole. This may be done fairly exactly by the author's new analytical method (1) which divided fixed acidity into two principal parts: — 1) acidity soluble in ether-alcohol, due to lactic, succinic, malic and citric acids; 2) insoluble acidity, including tartaric acid as cream of tartar and a slight additional acidity.

The author found lactic acid present in marked quantities in the wines he studied, even in those which had not been influenced by filiform ferments. The proportion of succinic acid does not vary much, whereas the figures for malic acid differ greatly, sometimes exceeding those for tartaric acid. Citric acid is sometimes present in fairly large quantities.

Anaerobic microorganisms, which cause the more or less serious diseases of wine, may cause the fixed acidity to vary considerably.

When wine turns sour, the tartaric and malic acids disappear fairly quickly, the one more completely than the other, whereas they remain more or less in bitter wine. This difference also depends doubtless on the initial composition of the wine as well as on the bacterial action; but, on the other hand, the ferments of sour wine being more active than those of bitter wine, it is possible that this action is on the lactic acid formed at the beginning, when tartaric and malic acids are absent in sour wine. Succinic acid appears to resist the influence of all ferments causing disease.

INDUSTRIES  
DEPENDENT  
ON PLANTS  
PRODUCTS

(1) *Comptes Rendus des Séances de l'Académie des Sciences*, Vol. CLXV, No. 23, p. 793-795. (Author).

213 - Contribution to the Study of Alcoholic Ferments. — KAYSER, E., in *Comptes Rendus des Séances de l'Académie des Sciences*, Vol. CLXV, No. 25, pp. 1020-1022. Paris, December 17, 1917.

Selected yeasts often have a great influence on the quality of fermented drinks. They also play a part in the secondary reactions, especially if left on the lees for a certain time; in the alcohols obtained there are distinct differences in the various components of the non-alcoholic coefficient.

At the end of a year an analysis of the fermentation products gave the following results:—

	Quantity per litre					
	wine yeast		cider yeast		perry yeast	
	1	1 a	2	2 a	3	3 a
Total acidity in malic acid . . .	5.84	10.92	6.47	10.54	6.99	10.92
Volatile acidity in acetic acid . .	0.142	0.071	0.368	0.110	0.052	0.065
Alcohol per cent in volume . . .	6.93	6.20	6.85	6.30	6.87	6.32

The same apple must, obtained from equal weights of the varieties Saulet, Lauquart, Cébin and Douce de Bretagne, was compared by adding to it a wine yeast (Champagne), a cider yeast (Cálvados) and a perry yeast (Eure). Fermentation took place in six flasks, to three of which (the three a) was added a sterile solution of ammonium phosphate.

The volatile acidity was composed of acetic acid and butyric acid with traces of formic acid. The addition of phosphate decreased the proportion of volatile acids. The proportion of butyric acid was higher for perry yeast, and especially for wine yeast, than for that of cider, *i. e.*, the phosphate increased the proportion of acids superior to acetic acid. It is known that phosphate also increases the amount of yeast.

The alcohols were redistilled and concentrated; their composition was found to be as follows:—

	Percentage of alcohol at 100°, in milligrams					
	1	1 bis	2	2 bis	3	3 bis
Volatile acidity in acetic acid . .	17.3	16.7	31.1	21.3	17.1	17.0
Aldehydes . . . . .	323.2	64.4	330.0	247.0	349.0	315.0
Furfural . . . . .	0.15	0.32	0.15	0.12	0.11	0.11
Ethers, as ethyl acetate . . . .	50.8	49.3	47.9	67.3	43.4	67.1
Higher alcohols . . . . .	364.0	245.0	167.0	153.0	213.0	159.5
Non alcohol coefficient . . . . .	755.45	375.62	576.15	488.72	667.61	559.61

It is seen that the three yeasts are distinctly different. In spite of slight contact with the air all produced much aldehyde; the addition of

phosphate decreased their proportion, especially for wine yeast. The ethers are present in small quantities as opposed to the aldehydes, but, in the case of cider and perry yeasts, were increased by the addition of phosphate. Wine yeast gave most higher alcohols, cider yeast the least; phosphate decreased them.

The impurities are, therefore, greatest for wine yeast, showing that a selected yeast, chosen in accordance with the aim in view, might be more advantageously used. Such yeasts must be used with a knowledge of their properties; among the various yeasts of wine and cider, there are doubtless some which would have acted differently from those used in the author's experiments without bringing in the important factor of custom.

214 - Contribution to the Study of the Alcohols of Cider (1). — KAYSER, E., in *Bulletin de la Société des Agriculteurs de France*, pp. 321-323. Paris, November, 1917.

In 1916 the author reported that high temperature increased the proportion of volatile acids, aldehydes, ethers, and higher alcohols in alcoholic fermentation. In this paper he describes his studies on the influence of the must, especially of its nitrogen content, on the formation of these substances.

Apple must, sterilised in the autoclave, and containing 10.4 % of saccharose, was subjected to fermentation. At the beginning of December, 1916, this was sprinkled with a strong yeast *a* and an apiculated cider yeast *c*. The experiments were made in three flasks which, when sprinkled with the yeast, were left in a cupboard at room temperature, which varied from 4 to 12° C. They were, thus, subjected to all the variations of the winter 1916-1917. Fermentation was slow.

In March 1916, *i. e.* 3 ½ months later, the liquid in the two flasks *A* and *C* was poured into two similar flasks. The operation was carried out aseptically, and care was taken not to disturb the lees at the bottom. The liquids were analysed (enough for this purpose remained at the bottom of the flasks, on the lees).

The contents of flask *A* were poured into an empty, sterile flask, *A'*; those of flask *C* into a flask, *C'*, which contained the same must fermented by a third yeast, *b*.

The experiment was continued: — Flask *A*, without yeast, flask *B* with lees formed from the beginning, flask *C* in contact with a new yeast which had still to finish its secondary fermentation.

In spite of the precautions taken during pouring, a few globules of the yeast *a* passed into the flasks *A'* and *C'*.

The experiment was interrupted after 6 months, *i. e.* towards the middle of June and the fermented liquids analysed. Corresponding alcohols were obtained by heating. Table I (on the following page) gives the results obtained.

These results show that fermentation was not quite identical, at the same moment, in the three flasks, although all the conditions were the same. This is often observed in laboratory experiments.

(1) See *R.*, December, 1916, No. 1320. (*Ed.*).

TABLE I. — *Results of analysis of the fermented liquids (per litre).*

	After 3 ½ months		After 6 months		
	A	C	A'	B	C'
Total acidity (sulphuric acid) . .	2.48 gm.	2.29 gm.	2.75 gm.	2.71 gm.	2.73 gm.
Volatile acidity (acetic acid) . .	0.598 gm.	0.501 gm.	9.678 gm.	0.534 gm.	0.427 gm.
Alcohol % in volume . . . . .	4.60	4.200	6.200	6.500	5.700
Reducing matter. . . . .	20 gm.	31.1 gm.	9 gm.	4 gm.	22 gm.

It should be noted, in particular, that the quantity of volatile acids has decreased for *C'* between the first and second analyses. It should also be noted that after 3 months of this slow fermentation, on account of the temperature, there still remained some undecomposed sugar, present in a larger proportion in *C* than in *A*, and that, even after 6 months, in spite of the presence of an active, re-invigorated yeast, there was still a good proportion of reducing matter per litre.

TABLE II. — *Analysis of the alcohols obtained.*

	Quantity per cent of alcohol at 100° in milligrams		
	A'	B	C'
Volatile acids (acetic acid) . . . . .	94	51	46
Aldehydes . . . . .	69	8.40	57.6
Furfural . . . . .	0.6	0.32	0.44
Ethers (ethyl acetate) . . . . .	89	97	110
Higher alcohols . . . . .	55.3	44.5	68.50
Non alcohol coefficient . . . . .	307.9	201.22	282.54

Table II shows that flask *B*. is the poorest in higher alcohols and aldehydes. It seems, thus, that decanting, which facilitated aeration, increases the content in higher alcohols and the formation of aldehydes. Decanting on to a new yeast decreased the volatile acidity and increased the ethers.

The non-alcohol coefficient, *i. e.* the total amount of impurities, is highest in flask *A'*, from which the lees were most carefully removed. All the non-alcohol coefficients are inferior to those obtained in practice with impure fermentations; this is not surprising.

Below are the usual ratios obtained from the study of the alcohols.

Flask	Ethers Acids	Ethers Higher alcohols	Total Alcohols + Ethers
A'	0.94	1.6	144.3
B	1.9	2.2	141.5
C'	2.3	1.6	178.5

The ratio  $\frac{\text{ethers}}{\text{acids}}$  increases from  $A'$  to  $C'$  because the volatile acids decrease without there being a proportionate increase in ethers. The proportion  $\frac{\text{ethers}}{\text{alcohols}}$  is the same for the flasks  $A'$  and  $C'$ , being higher for the undecanted flask, which has a lower content of higher alcohols.

The total "alcohols + ethers" is highest in the flask  $C'$ , where the secondary fermentation was made with a new yeast. It is thus possible to see the influence of the new yeast, as well as that of an almost complete absence of yeast, in other words, the effect produced by decanting flasks  $A$  and  $C$ .

There is no doubt that in practice the results would have been similar, with, perhaps, less marked differences.

These experiments show also that cider for drinking and cider for distilling must be treated differently. It is clearly not a question of diseased ciders, with which frequently the only thing to be done is to turn them into alcohol. It is also probable that the variety of yeast is of great importance from this point of view.

215 - **The Production of War Alcohol with Perry Pears.** — TRUELLE, A., in *Comptes rendus de Séances de l'Académie d'Agriculture de France*, Vol. III, No. 31, pp. 913-924. Paris, October 17, 1917.

Most of the early and semi-early perry pears become over-ripe very quickly. It is, therefore, necessary, to make the best use of them, to apply a rational treatment which will delay over-ripening as long as possible — storage at a low temperature by piling in well-ventilated lofts, or better still, spreading in the open air on faggots in a shed or under a roof sheltering them from the rain and sun. The piles must not exceed a height of  $19\frac{1}{2}$  to  $24\frac{1}{2}$  inches. The fruit must, moreover, be very carefully watched so as to note when it begins to turn sleepy, so that it may be used, at the latest, before the endocarp is attacked.

The best use of sleepy pears is to turn them into alcohol, but this can only be done by means of suitable treatment of the fruit and juice. It is particularly important that the clear juice ferment rapidly and completely by the use of leaven or pomase prepared with native yeasts, or selected yeasts.

To obtain a clear juice the sleepy pears must be pressed in separate layers, not more than 4 to 6 inches thick, inclosed, if possible, between thick canvas and separated one from the other by draining-hurdles, or, in the absence of canvas and hurdles, by beds of long straw, or very clean reeds. If, after the first pressing, the residue contains many fragments of pulp, it is crushed; otherwise it is crumbled and pressed again; in no case is it diluted with water. The two juices obtained are put in a very clean, unfumigated cask and sprinkled as soon as possible.

The leaven is prepared with two leavens, 20 to 30 litres of mother leaven, and about 100 litres of a stock leaven; it is this latter which is finally added, the first being used to prepare it. : —

The technique of the method used by brewers to prepare the leaven is

described and emphasis is given to the necessity of distilling so as to produce the greatest quantity of well flavoured alcohol of the highest quality. The most reliable method of succeeding is to use a rectifying still, giving alcohols of 60° to 75° passing over first,

The author comes to the following conclusions : —

From a chemical point of view, sleepy pears contain less sugar, tannin and acid than sound pears, but more pectic matter. From an economic point of view, considering only two important factors influencing their value — gross weight and sugar — during over-ripening they lose much weight the loss varying, according to the variety and duration of over-ripening, between  $\frac{1}{11}$  and  $\frac{1}{5}$  of their total weight, and between about  $\frac{1}{3}$  and  $\frac{2}{5}$  of their total sugar content. Such a loss, expressed in 100° alcohol, is equal, in round figures, to a deficit of from 7 to 25 litres per metric ton of sound pears.

Under present conditions, so as to lose nothing which may be of use to the national defence, every grower should turn his sleepy pears into alcohol. This is, nevertheless, only a means of avoiding total loss as, otherwise, such pears have no commercial value, but it is of far greater importance to use them while they are sound as then they yield a better and more abundant product.

216 — **On Chalk Bread.** — LEPICQUE, L. and LEGENDRE, R., in *Comptes rendus des Séances de la Société de Biologie*, Vol. LXXX, No. 19, pp. 896-897. Paris, December 8, 1917.

With reference to M. RAPHAEL DUBOIS' note (1) in which he proposes to add to coarsely bolted flours used in breadmaking calcium carbonate instead of caustic lime water which he said "kills the yeast", the authors state that, in their opinion, caustic lime is preferable.

Lime water, they say, does not kill the yeast, save when mixed with it directly before it is added to the dough. If, however, the amount of alkali is so calculated as to neutralise the flour incompletely, the lime method gives the dough a slightly acid reaction which appears to be the optimum condition for the yeast, whereas the acid fermentations are inhibited by a preceding decrease of acidity. When the leaven only is used there is no danger, with lime water, of exceeding the point of neutralisation. If the leaven is strengthened by the addition of grain yeast, it is sufficient to dilute this yeast in tap water; it is then added to the dough, from which the alkalinity of the lime has disappeared.

The difference between the quantities of chemical product added is: — with lime water, a maximum of 30 cgms. per kilogram (2.2 lbs.) of bread; with calcium carbonate, 15 to 20 gms.; even if reduced by half this last proportion will doubtless appear excessive for a food such as bread.

218 - **The Cotton Industry in China.** — From the "North China Herald" in *The Agricultural Journal of India*, Vol. XII, Part IV, pp. 658-661, Calcutta, October, 1917.

China's importations of cotton from foreign countries are increasing and will continue to increase, because the finer yarns cannot be spun from Chinese cotton. Shensi cotton, which is an American strain introduced into China, is about the only Chinese cotton that can produce a finer yarn than 16's and at the same time obtain a satisfactory production; and what China needs is more cotton of the Shensi type, or finer.

China's export cotton trade is a considerable one and about half of the exported cotton goes to Japan.

There is a special grade of cotton peculiar to Shantung in much demand in America, where it is prepared as medicated cotton, for which it is especially adapted, as it is so white that it requires no bleaching. It is a short fibre and harsh to the touch, so it makes an admirable imitation wool, either when used alone or mixed with wool in the manufacture of cheap hosiery and underwear.

Considering the remarkable growth of the local spinning and weaving industry during very recent years, it is only reasonable to expect that the future will see Shanghai developed into the Manchester of the Far East, provided, however, that the manufacturers are given reasonable protection so that they may be allowed to compete on a fair level with foreign mills. Given this protection, the possibilities for expansion seem almost unlimited, when it is considered that all of China's millions are clad in cotton clothing. That there is ample room for vast increase in the number of power-driven spindles and looms, may be judged from the following estimated figures for the three Far Eastern countries, interested in cotton mills:

	Population	Spindles	Looms
China . . . . .	400 000 000	1 050 000	5 000
India . . . . .	278 000 000	6 400 000	28 000
Japan . . . . .	52 000 000	2 414 544	24 000

Japan, a non-cotton growing country, has succeeded in developing the mill industry to such an extent in 25 years, through a protective tariff, which places raw cotton on the free list and heavily taxes manufactured cotton when imported.

Modern cotton manufacturing was introduced into China in 1890 and was extended considerably in 1896 and 1897, when foreign capital was put into local mills. Up to 1902, however, there were no returns on the investments, owing to the rapid increase of spindles and the inefficient supply of native cotton, which was not equal to the demand, and the fact that the price of raw cotton, because of the shortage, increased out of proportion to the price of yarn. The demand for the raw material, however, was met by increased acreage, and the mills have been more prosperous during recent years.

Since the organization of the Shanghai Cotton Testing House in 1911, the testing of cotton against water and other adulteration has led to very beneficial results during the past few years. The associated mills, under the

rules of the House, are not allowed to accept cotton carrying over 15 per cent. water, and an effort is being made to keep the moisture down to 12 per cent.; the natural moisture carried by American cotton is 8 per cent., and in China commonly it is 10 per cent. although Shensi cotton is naturally so low as 9 per cent.

China grows cotton and exports half to Japan, whence it is returned in the form of yarn and cloth which could be made in China. When the mills in Shanghai use Shensi, Shantung, Hupeh, or other cotton not grown in this province, at the port of entry the customs levy a duty of HK. Tls. 0.35 per picul (1), and again HK. Tls. 0.175 per picul import duty at Shanghai, in all HK. Tls. 0.525. The mills naturally avoid, so far as possible, using cotton from other than their own districts, with the result that a large part of the crop raised in provinces not adjacent to Shanghai is exported and returned to China in manufactured goods. The demand for foreign cotton, which is indispensable for certain purposes, is increasing annually, but the duty the mills have to pay on the imported cotton constitutes a considerable obstacle to the further development of the industry.

221. — **Investigations into the Proteolytic Activity of Lactic Ferments (2): — III. The Influence of the Method of Milk Sterilisation; IV. Lacto-culture in the Selection of Lactic-Proteolytic Ferments.** — GORINI, COSTANTINO, in *Atti della Reale Accademia dei Lincei, Ser. V, Rendiconti di Scienze fisiche, matematiche e naturali*, Vol. XXVI, Pt. 7 and 8, pp. 195-199 and 223-227. Rome, 1917.

The increasing importance of lactic ferments, not only in agriculture (cheese industry, silage), but also in medicine (surgical and intestinal infections) should induce workers to continue to study the differentiation and selection of species best adapted to particular functions and to cultivate them so as to obtain the greatest possible benefit.

As the author showed long since, the lactic ferments differ less in their morphological characters than in their bio-chemistry, so that one ferment cannot be used indifferently for another in cheese making or ensiling fodder.

Apart from their acidifying capacity lactic ferments also possess another very interesting faculty — their proteolytic activity, to which the author has already drawn attention by pointing out its scientific and practical-importance for either the ripening of cheese or silage or for intestinal bacteriotherapy. The proteolytic activity of lactic ferments has been largely misinterpreted as a result of unsuitable experimental conditions. Since the author has made known the inhibitory influence exercised on this activity under such conditions (especially the incubation temperature and

(1) The Hai-Kwan-Tael of the Customs weighs 37.72 grams and had in 1913 an average value of 3.81 fr. A Pikul of 100 chin is equal to 60.453 kg. (Ed.)

(2) See also R., Jan., 1916, No. 109; R., Feb. 1916, No. 232 (Ed.)

the nature of the culture medium), other workers have modified and rectified their opinions, and types of lactic ferments formerly considered to have no peptonising power are now acknowledged to possess it.

Another source of error which must be eliminated is the excessive temperatures generally used when sterilising milk for lactic ferment cultures, as these turn the milk brown and affect the casein. Milk sterilised too long or at excessive temperatures is not suited to the casein-peptonising action of lactic ferments. (This is probably one of the motives causing workers to disagree with the author as to the importance of certain bacteria of cheese, the udder, etc.).

To make an exact study of the biochemistry of lactic ferments the milk must be sterilised with precautions which, as far as possible, will enable it to keep its white colour. This result may be obtained with an autoclave, or, better still, a current of steam, at a temperature not exceeding 100° C. and by fractional sterilisation for 1 to 20 minutes during 3 consecutive days. It would be preferable to use temperatures below 100° C., but in this case the milk must be taken aseptically. In all cases the sterilised white milk must be carefully examined to make sure it is free from microorganisms.

Only when, by the improved cultural technique devised by the author, it has been possible to separate and set in motion the proteolytic capacity of a given lactic ferment, will it be possible to differentiate this ferment, and for the selector to appreciate and utilise it either in agriculture or medicine, where, not only the acidifying capacity, but also the products of proteolysis (albuminoids, peptones, amino-acids) of the ferments used must be taken into consideration.

**222 - The Dairying Industry in South Africa.** — BAYNES, JOSEPH, in *The South African Journal of Industries*, Vol. I, No. 2, pp. 124-126. Pretoria, October, 1917.

Of recent years the dairying industry in South Africa has progressed considerably. Whereas, in 1906, the Union imported 11 273 748 lb. of butter, in 1909, 4 512 895 lb., in 1912, 4 925 188 lb., in 1915, 2 026 258 lb.; in 1916 the importation was reduced to 267 896 lb., and, up to the end of June, 1917, 2  $\frac{3}{4}$  million pounds had been exported to the London markets. The number of manufacturing dairies had risen to 53, that of the collecting centres to 10 in active operation. The cheese industry has made similar progress to a small extent; the importation of cheese fell from 5 586 244 lb. in 1913 to 2 028 508 lb. in 1916, and is continually decreasing. South Africa now produces over two million pounds of cheese equal in quality to the best imported cheese.

It seems that before long the condensed milk industry will make such progress as to render unnecessary all importation of this article, which before the war reached a value of £ 500 000.

Moreover, pig-breeding and the production of bacon and lard, the importation of which reached a value of £ 224 614 in 1916, may in future be quite independent of outside help, especially if the farmers perfect the breeds and produce a sufficient supply of suitable material for the bacon curing factories which are about to be established.

New Zealand is quoted as an example for South African farmers; this colony, with a smaller population than the Union, exported in 1914 42 000 000 lb. of butter, not to mention the other products for which it is famed. The price of good dairy land in New Zealand today is about £ 50 per acre, a price much above those realised in South Africa, where the land may well bear comparison with that of New Zealand in fertility and productivity.

The development of the dairy industry in South Africa still demands great attention with regard to the improvement of dairy stock, sweet cream and winter feeding. The movement for cow-testing associations should be encouraged in every way, so that farmers may be convinced that it is more advantageous to keep one good cow than three inferior ones.

The production of the best quality cream is of vital importance for the industry if South Africa is to compete satisfactorily with the other Dominions in superior quality products. The Dairy Bill, now under consideration, when passed, will control the improper grading of dairy products and protect alike the farmer, manufacturer and exporter against fraud.

223 - **Photographic Analysis of Dried or Fresh Eggs.** — LE ROY, GEORGES A., in *Comptes Rendus des Séances de l'Académie des Sciences*, Vol. CLXV, No 25, pp. 1026-1028. Paris, Dec. 17, 1917.

In the trade, to differentiate eggs as regards freshness or more or less good state of preservation, the candling method is used *i. e.*, an optical examination by transparency, based chiefly on the size of their air space.

For legal purposes, the author devised a new method which is more exact, allowing the size of the air space to be gauged, and a graphic record to be taken, so as to form a convincing proof, which will be both lasting and suitable for purposes of comparison. The result is obtained by photography, together with special adjustment of the light and arrangement of the eggs, which are fully described, and extremely sensitive plates. By this method it is possible to obtain life-size photographs, by transparency, of groups of eggs and their air spaces, which may be measured by a graph placed over, or forming part, of the photograph.

The use of radiography for this purpose only gives deformed images very inferior to those obtained by the photographic method.

224 - **Dried Eggs (1).** — LINDET, in *Comptes Rendus des Séances de l'Académie d'Agriculture de France*, Vol. III, No. 40, pp. 1116-1119. Paris, December 19, 1917.

For some time past there have been on sale at Paris dried eggs from Hang-Tcheou (China), where an American factory, using a method already practised in Chicago, has been established.

The author does not know the method adopted, but does know that the water is evaporated at a temperature below 50-55° C. Egg albumen coagulates at 50-55°, and the author found in these eggs a quantity of uncoagulated soluble albumen, representing 30 % of the dry product, whereas eggs of normal composition have from 36 to 37 %; the albumen, therefore, is

(1) See also R. 1916, No. 1224. (Ed.).

not coagulated. To obtain a commercial evaporation at 50-55° C a mercury depression of 65-70 cc. is required; evaporation is, therefore, carried out in an almost complete vacuum. It is possible that a procedure is adopted similar to that proposed by MESSRS. BEVENOT and LENEVEU for the dessication of milk, which consisted in powdering the milk in a chamber the walls of which were heated.

The composition of these eggs is identical with that of normal eggs supposed to be dry. The author found 46.9 % of nitrogen, 42.4 % of fat; 3.5 % of salts; 7.2 % of moisture. The fact that the nitrogen and fat are present in almost equal proportions shows the eggs to be whole. The product contains no antiseptic.

One box contains the product of 12 eggs, weighing 150 gms., that is to say 139.2 gms. of chemically dry eggs, equal to 530 gms. of fresh eggs, or 12 eggs of 45 gms.

This egg powder will not keep an indefinite time; the fat easily becomes rancid. The product is shipped in refrigerators, and, while awaiting sale, is kept in cold storage at Clichy.

In the military hospitals of Paris, the chemists of which have all given a favourable report, these dried eggs are largely used and greatly appreciated.

225 - Production and Use of Pigskin: — See No. 191 of this Review.

226 - The Handling and Storage of Spring Wheat. — BAILEY, C. H., in the *Journal of the American Society of Agronomy*, Vol. IX, No. 6, pp. 275-281, 5 diagrams. Washington, D. C., Sept., 1917.

Certain factors influencing the handling and storage of grain depend greatly on whether it is handled in bulk or in sacks. The storage of grain in bulk reduces the change in moisture content which is chiefly dependent on the climatic conditions prevailing between harvesting and threshing. If this period is warm and dry the grain will be well cured when it is sent to the consumer, but, if rain falls on the unthreshed bundles, especially on shocks, the wheat will be damp and tough, and, consequently, more difficult to handle and store.

Wheat assumes the temperature of the surrounding medium more rapidly when stored in sacks than in bulk, so that, in the first case, it is less subject to injury from fermentation.

Spring wheat is not biologically ripe at the time it is usually harvested. The process of ripening after the harvest is accompanied by certain peculiar phenomena. If the bundles are in a stack they absorb the moisture. This process, commonly called "sweating", is undoubtedly accompanied by biochemical changes resulting from enzymic activities within the kernel. If this sweating process occurs in normal wheat in the bin, a slight rise in temperature may result. The baking quality of the flour is improved by these changes in the grain.

Several factors determine the keeping quality after sweating; the most important of these is its moisture content at the time of storage. It is probable that, in dry grain, the amount of water absorbed is not sufficient

TRANSPORT,  
TRADE

to produce a gel, *i. e.* the colloidal material does not have a continuous structure, thus greatly reducing the possibilities of diffusion.

The exact percentage of moisture below which this discontinuous structure exists is not known; it probably varies with the percentage of gluten in the grain as gluten has a greater water-absorbing power than starch. Increasing the moisture content above the maximum at which discontinuity exists results in the formation of an elastic gel through which diffusion can take place. Further increases in moisture content up to saturation (maximum absorption) produce progressively less viscous gels with a corresponding increase in the rate of diffusion. Since the rate of respiration in grain doubtless depends in part on the rate of diffusion between the various kernel structures, it follows that the less viscous the gelatinous material of which the cell contents are composed, the more rapid is the production of heat through respiration. For these reasons the susceptibility to heating of grain stored in the bulk is largely determined by its moisture content.

To ascertain the percentage of moisture which spring wheat may contain without heating in store, the Minnesota Grain Inspection Department and the State Board of Grain Appeals, in cooperation with the Division of Agricultural Chemistry of the University of Minnesota, made observations on the wheat stored by one of the large elevator companies. About 20 lots of wheat, containing from 12.76 to 17.45 % of moisture, were examined. The observations lasted over a year, from one summer to the following summer. From the results it was concluded that hard spring wheat, of reasonable plumpness, containing less than 14.5 % of moisture is not likely to heat when stored under normal conditions in a temperate climate, whereas similar wheat, containing 15.5 %, or over, of moisture is practically certain to heat. Between these limits the possibilities of heating depend on the following conditions: — the percentage of moisture, temperature of the atmosphere, position of bin in the elevator (the grain keeps better in the outside bins than the inside ones), material of which the bin is constructed, initial temperature of the wheat (the curve illustrating the acceleration of respiration with a rise in temperature is logarithmic), size or dimension of the bulk, etc. In uniformly mixed wheat the highest temperatures are usually near the surface; when the surrounding air is cold, as in midwinter, the maximum temperature is usually from 15 to 20 feet below the surface; in mild or hot weather, it is found at a depth of from 5 to 8 feet.

227 - **Substitutes for Tin Cans.** — *The Tea and Coffee Trade Journal*, Vol. XXXII No. 6, pp. 536-540. New York, June, 1917.

Owing to the shortage of tin and the consequent inability of tin can manufacturers to meet fully the needs of their customers, attempts have been made to replace this metal by various paper, fibre and composite products. Manufacturers of such materials declare that their boxes preserve and carry dry products as well, and in some cases better, than all-tin boxes. The types of packing now in use may be divided into five: —

1) **Cardboard.** — This is now generally used for packing tea and coffee, especially for medium qualities, many firms reserving their tin boxes

for the best qualities only. It has been said that coffee packed in cardboard loses its aroma, but this may be prevented by the use of impermeable wrappers. The increasing popularity of cardboard is undoubtedly due to its low cost and adaptability to modern packing machinery.

2) *Paper*. — In spite of its increasing price paper is the cheapest wrapper now on the market. It may be made very attractive and is being used more and more extensively every day. It is regularly used for flour, cereals, spices, cocoa, chocolate, drugs and sugar.

3) *Fibre*. — This class includes the cylindrical box used by the QUAKER OATS COMPANY; it is made entirely of fibre board with a slip cover. As the fibre is not treated in any way, a liner is usually considered necessary. This packing may be made to look practically like a tin box, and is much in demand by manufacturers who wish to imitate as nearly as possible the old tin cases.

4) *Paraffined fibre*. — Paraffined packing is rapidly coming to the fore. All the models have an outer covering of paraffin, the manufacturers claiming to have special processes by which the paraffin is made to penetrate the pores of the paper. These cases are substantial in appearance and are made in a variety of shapes. It is claimed that the paraffin adds considerably to the flavour-retaining properties of the package, as well as making it moisture-proof.

5) *Composite*. — By this name are known boxes of fibre with tin tops and bottoms. This model is made in various shapes and combines the advantages of cardboard with those of tin. The metal parts increase the rigidity and durability of the packing, whereas the fibre sides eliminate the necessity of labelling by allowing designs and lettering to be stamped on the material.

The shortage of tin has also increased the demand for wood and fibre shipping cases. There are many models in sizes varying from 25 to 200 lbs. capacity. The prevention of loss through moisture or odour is specially aimed at.

A list of American manufacturers of boxes in cardboard, paper, fibre, etc. is given.

## PLANT DISEASES

### DISEASES DUE TO FUNGI, BACTERIA AND OTHER LOWER PLANTS.

#### GENERAL

228 - Fungi from Tropical Africa, California and New Zealand. — WAKEFIELD, F. M., in *Royal Botanic Gardens, Kew, Bulletin of Miscellaneous Information*, Nos. 9 and 10, pp. 308-314, figs. London, 1917.

The paper under review includes eight species of fungi, known or suspected to be parasites. Three of them, *Polyporus coffeae*, *Helicobasidium longisporum* and *Cercospora cannabina*, occur on economic plants, and may prove to be of some importance. The parasitism of the two first has not been proved, but it is possible that *Helic. longisporum* at least may be capable of causing injury. The specimens examined by the author are the only ones reported so far.

The list includes the following species, the diagnosis of which is given in latin:—

1) *Polyporus Coffeae* Wakef., at the roots of a dead coffee tree at Kampala (Uganda); it is suspected of having caused the death of the tree; the fructifications were found surrounding the collar of the plant, the roots of which were encrusted with a layer of white mycelium mixed with sand; on this crust were conidial fructifications which may be connected with the *Polyporus*;

2) *Amauroderma infundibuliforme* Wakef., on the ground beneath a dead tree, Bumpenge Forest (Uganda);

3) *Hexagonia subvelutina* Wakef., on wood, in the East Africa Protectorate;

4) *Helicobasidium longisporum* Wakef., on roots of *Theobroma Cacao*, in Uganda, the affected roots show internal mycelium, especially along the medullary rays; MR. W. SMALL, who found the fungus, is inclined to consider it parasitic;

5) *Tilletia Wilcoxiana* Griffiths, on a specimen of *Stipa eminens* var. *Andersonii* Vasey, from Santa Catalina Island (California), and preserved in the Kew Herbarium;

6) *Uromyces Secamonae* Wakef., on leaves of *Secamone platystigma*, in Uganda ;

7) *Puccinia Hoheriae* Wakef., on leaves and stems of *Hoheria populnea* (Lacebark), New Zealand ;

8) *P. Berkheyae* Wakef., on leaves of *Berkheya Spekeana*, in Uganda ;

9) *Puccinosira Dissotidis* Wakef., on leaves of *Dissotis incana* and *Dissotis* sp., in Uganda ; this is the only species of *Puccinosira* for which an aecidium stage has been described (*Aecidium Dissotidis* Cooke) ;

10) *Cercospora cannabina* Wakef., on leaves of *Cannabis sativa*, in Uganda.

229 - Selected Danish Barleys Resistant to *Ustilago Hordei*, *U. nuda* and *Septoria graminum*, Introduced into the United States of America. — See No. 138 of this Review.

RESISTANT  
PLANTS

230 - A Rust-resistant, Danish *Festuca elatior*, Introduced into the United States of America. — See No. 138 of this Review.

231 - "New Era", a New Zealand Potato Resistant to Mildew. — See No. 138 of this Review.

232 - On Forms of the Hop (*Humulus Lupulus* L.) Resistant to Mildew (*Sphaerotheca humuli* D. C. Burr.) (1). — SALMON, E. S., in *The Journal of Agricultural Science*, Vol. VIII, Pt. 4, pp. 455-460. Cambridge, December, 1917.

In certain seasons, such as 1916, very severe losses are caused to the hop-crop by attacks of the mildew *Sphaerotheca Humuli* (DC) Burr. Within recent years the hop-mildew has also appeared in epidemic form in the United States. The fact that certain forms of the hop-plant are very resistant to *Sph. Humuli* is, therefore, of great scientific and economic interest.

While the morphological species of *Sph. Humuli* attacks a very large number of host-species belonging to many different genera, experiments have proved that a specialisation of parasitism has taken place, and that the form on *Humulus* constitutes a "biologic form" with the power, so far as is known, of infecting only species of this genus.

Resistance to hop-mildew was first observed during the summer of 1914 at the South-Eastern Agricultural College, Wye, Kent. Several hundred one and two year old seedling hops were grown in pots in a greenhouse under conditions which ensured their being attacked by mildew. Of these plants, two proved immune throughout the growing season in spite of repeated attempts to infect them directly and indirectly. These plants were grown from seed of a hop found wild in hedges at Vittorio (Treviso, Italy) collected in October 1913 by Prof. P. A. SACCARDO. About 70 other seedlings of the same origin, the same age and grown under conditions identical with those of the first two, proved very susceptible to mildew.

During 1916 the same resistance to mildew was noticed in 7 others of the same Italian origin and of the same age as the immune plants observed in 1914. Whereas these seven plants remained immune throughout the

(1) See also R. Dec., 1917, No. 1142. (Ed.)

growing period, 150 seedlings of the same age and origin, grown in the same greenhouse, proved very susceptible to mildew.

The same complete immunity was shown in 1916, under the same conditions, by three plants of a form of *Humulus Lupulus* with yellow leaves, received, under the name of "golden hop", from Messrs. Bide and Sons of Farnham, who had bought it from Mr. G. Benard of Orleans.

The two seedlings found to be immune in 1914 were planted out during the winter 1914-15. They developed normally and, in 1916, flowered; it was then seen that one plant was male, the other female. Throughout the summer and early autumn these seedlings showed no trace of mildew although all the surrounding hops were attacked. Nevertheless, by October 3, a few leaves and flowers of a late shoot of the female plant, and two leaves, each on one of two late lateral shoots of the male plant, showed small patches of mildew.

In 1902, NEGER pointed out the possibility of the existence of "immune races" among host-species susceptible to mildew, and described instances where individual plants of *Spiraea Ulmaria* and *Epilobium montanum* resisted all infection from the conidia of *Sph. Humuli* which had developed on the same host-species.

According to Prof. KINGO MIYABE, the "biologic form" of *Sph. Humuli* which attacks *Humulus* does not exist in Japan, although the species *Sph. Humuli* is very common there on a certain number of host-species belonging to different genera. In 1916, the author received from Prof. MIYABE specimens of the male plant of the wild hop of Japan (*H. Lupulus* var. *cordifolius* Maxim). When grown in the greenhouse where, as already stated, the conditions were favourable to inoculation by conidia of the form of *Sph. Humuli* which lives on hops, the plants were infected.

A similar case is undoubtedly that of the "immunity" of Virginia creeper (*Vitis hederacea*) in Europe. In the United States this plant is attacked by vine mildew (*Uncinula necator* [Schwein.] Burr.). This mildew is very common in Europe on cultivated vines, but, within the author's knowledge, has never been found attacking Virginia creeper, doubtless because specialisation of parasitism has occurred in the species *U. necator* and the "biologic form" attacking *Vitis hederacea* has not yet reached Europe.

At the present time there are no restrictions in England on the importation of *Vitis hederacea* from America. To protect this plant from the danger of being attacked by mildew, the English authorities should prohibit this importation or inspect the imported plants closely.

MEANS  
OF PREVENTION  
AND CONTROL

DISEASES  
OF VARIOUS  
CROPS

[232-235]

236 - **The South American Hevea Leaf Disease in Trinidad.** — RORER, J. B., in *Bulletin of the Department of Agriculture, Trinidad and Tobago*, Vol. XVI, Pt. 3, pp. 128-129, Port of Spain, 1917.

In July, 1916, the author's attention was called to a disease of the leaves of hevea trees (*Hevea brasiliensis*) which was causing considerable defoliation on many different estates in widely separated parts of Trinidad. Microscopic examination showed the disease to be the South American Hevea Leaf Disease, which, judging by its general distribution, must have existed in the island for several years, but only became epidemic in July, August and September, 1916, when the climatic conditions were exceptionally favourable to fungous growth.

The disease was first reported in Surinam (Dutch Guiana) in 1910, and was carefully studied by Dr. KUIJPER, who published a report on it in 1912. At that time the disease was confined to nursery stock and young trees, while the older plantations seemed quite free from infection. During the past four years, however, both in Surinam and Demerara (British Guiana), the disease has spread rapidly to the older Hevea trees, and must now be considered as the most serious disease of this plant in that part of the world.

Dr. GEROLD STAHEL, Mycologist to the Department of Agriculture of Surinam, has made a long and careful study of the disease. He has determined that it is caused by a fungus with three different fruiting stages, only one of which spreads the fungus. This form belongs to the genus *Scolecotrichum*, and its spores are produced in abundance chiefly on the under side of the very young, diseased leaves. These spores, carried by the wind, rain or insects, germinate and penetrate the young tissues of the leaves very rapidly (10 hours), and thus cause widespread epidemics under suitable weather conditions. After 15 hours' drying they lose their germinating capacity.

- The other two forms of the fungus occur on or around the edge of the spots on the older leaves. They appear as small, black pustules, similar in external appearance, but some contain spores of one kind, some spores of another kind. Dr. STAHEL's work shows that these two types of spores are only very slightly capable of infecting the leaves, and may be entirely disregarded as a cause of the spread of the fungus.

Dr. STAHEL states that very many rubber trees in Surinam are attacked by this disease, and that, on parts of some estates, as many as 20 % of the trees have been killed by it. According to BANCROFT the disease is also widespread, virulent and epidemic in Demerara.

No successful means of fighting the disease on large trees has yet been found. When it attacks nursery stock or young trees in the field it may easily be controlled by spraying with Bordeaux mixture.

The disease occurs in several districts in Trinidad, and was more widespread in 1917 than in the preceding year. In June 1917, the author visited a number of plantations and found the trees in normal condition. Nevertheless, in one or two places where the disease was not prevalent in 1916, the trees were badly attacked; one or two old trees were killed by the re-

peated attacks, and a number of two and three year old trees died on account of the repeated defoliation.

The disease does not appear to be so virulent in Trinidad as in Surinam and Demerara, probably on account of the less favourable climatic conditions for fungous growth; nevertheless it must be considered as a latent menace to the rubber industry in the island.

Spraying large rubber trees is practically out of the question on account of the expense; for this reason it is important to find and grow resistant individuals or varieties. As is now being done elsewhere, seeds should be selected in Trinidad from the trees giving the highest yields of latex, so as to use them for future plantations.

237 - **Endrot of Cranberries** (1). — SHEAR, C. L., in the *Journal of Agricultural Research* Vol. XI, No. 2, pp. 35-42, figs. 1-3, plate A. Washington, D. C., October, 1917.

i A disease of cranberries (*Oxycoccus macrocarpus*), called "endrot" is reported. It is caused by a sphaeropsidaceous fungus which does not appear to have been described previously and which is provisionally placed in the genus *Fusicoccum* under the name of *F. putrefaciens*.

The disease has been observed in all the cranberry-growing districts of the United States (Massachusetts, Maine, New Jersey, Michigan, Wisconsin, Washington, Oregon), and of recent years has caused considerable loss of the Late Howe variety, as well as attacking other varieties (Bennet Jumbo, Cape Cod Beauty, Early Black, Early Ohio, Mathews, Mc Farlin, Perry Pride, Prolific, Searles Jumbo, Selected Howe, Vose Pride, etc.).

The rot caused by the parasite usually starts as the blossom or stem end of the berry, hence the common names "blossom end rot" and "stem end rot", now replaced by the simple term "endrot". The fruit attacked eventually softens all over.

Only the pycnidial form of *F. putrefaciens* has been produced in culture. Dried, rotten, mummified berries, apparently destroyed by *F. putrefaciens*, left exposed in the field and examined after about a year and a half, showed a discomycetous fungus which is believed to be the perfect form of the parasite and which agrees very closely with *Cenangium urceolatum* Ellis.

Cultures of the mycelium show a characteristic series of colours and produce fertile pycnidia, more frequently on *Melilotus alba* than on other media.

Spraying experiments in Massachusetts show that this rot can be largely controlled by the use of Bordeaux mixture.

Some injury to the cranberry vines was noticed at the Massachusetts Cranberry Experiment Station at East Wareham which it was thought might be due to the use of Bordeaux mixture. The real cause of this injury, which was not found in other districts, is being investigated.

238 - **Watermelon Diseases in U. S. A.** — ORTON, W. A., in U. S. Department of Agriculture, *Farmers' Bulletin* 821, pp. 18, figs. 12. Washington, D. C., May, 1917.

A brief description of the diseases of watermelons (*Citrullus vulgaris*), particularly those found in the south-east of the United States, together with the methods of control, is given.

(1) See also R. April, 1916, No. 470. (Ed.)

The most common and most serious diseases are : —

- 1) wilt (*Fusarium nivium* Erw. Sm.) ;
- 2) root-knot (*Heterodera radicleola* [Greef] Muller) ;
- 3) anthracnose (*Colletotrichum lagenarium* [Pass.] Ell. and Halst.) ;
- 4) stem-end rot (*Diplodia* sp.).

The watermelon is also occasionally attacked by the following minor diseases : —

- 1) stem blight (*Mycosphaerella citrullina* [Sm.] Gr. ;
- 2) bacterial wilt (*Bacillus tracheiphilus* Erw. Sm.) ;
- 3) downy mildew (*Peronosplasmopara cubensis* [B. and C.] Clint) ;
- 4) malnutrition, attributed to lack of potash ;
- 5) blossom-end rot, probably due to defective pollination ;
- 6) ground rot (*Sclerotium Rolfsii* Sacc.).

## WEEDS AND PARASITIC FLOWERING PLANTS

239 - ***Kennedya rubicunda*, a Leguminous Plant Injurious to Forest Trees in New South Wales.** — MAIDEN, J. H., in *The Agricultural Gazette of New South Wales*, Vol. XXVIII, Pt. 10, p. 714. Sydney, October, 1917.

*Kennedya rubicunda* Vent., a native plant of Australia, very common in the coastal district of New South Wales, has recently been reported by MR. G. F. MCPHERSON, District Forester at Wyong, as being very abundant in the forests of that neighbourhood. It is found especially on improved, areas, where it attacks and covers the young hardwood trees in a very short space of time. It is feared that the plant will become a danger to the forests by retarding the growth of the young trees.

240 - **Methods for the Control of "Wild Rice" in Italian Ricefields.** — See No. 161 of this Review.

## INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

241 - **Observations on Animal Pests of Cultivated Plants, Made in Sweden from 1912 to 1916.** — TULLGREN, ALBERT, in *Meddelande No. 152 från Centralanstalten för försöksväsendet i Jordbruksområdet, Entomologisk Avdelningen* Nr. 27, pp. 1-104. Stockholm, 1917.

GENERAL

Thanks to the collaboration of many correspondents the Entomological Department ("Entomologisk Avdelningen") of the Central Experiment Station at Stockholm is able to collect and study material from all parts of Sweden, report the presence of destructive species, and study and make known the best means of control. The correspondents, 567 in number, are distributed as follows : — Malmöhus, 31 ; Kristianstads, 22 ; Blekinge, 10 ; Halland, 19 ; Kronoberg, 19 ; Jörrköping, 26 ; Kalmar, 27 ; Gotthland, 12 ; Östergötthland, 41 ; Skaraborg, 28 ; Alvsborg, 36 ; Göteborg and Bohus, 28 ; Örebro 22 ; Södermanland, 48 ; Västmanland, 14 ; Upsal, 28 ; Stockholm, 28 ; Värmland, 18 ; Kopparberg, 22 ; Gävleborg, 19 ; Jämtland, 24 ; Västernorrland, 16 ; Västerbotten, 19 ; Norrbotten, 10.

The publication under review gives data bearing on the period 1912-1916, during which not less than 345 animal species have been reported, distributed as follows : — orthoptera, 4 ; thysanoptera, 3 ; hemiptera, 41 ;

coleoptera, 85; lepidoptera, 106; diptera, 28; hymenoptera, 30; total number of insects, 297; myriapoda, 2; acarina, 19; snails, 1; nematodes, 2; birds, 14; mammals, 10.

Below are mentioned the species reported as new, or, on account of the damage they cause, deserving of special mention:—

*Gryllotalpa gryllotalpa* L. ("mullvadssyrsan") although relatively common in southern Sweden had not, for 25 years at least, caused such serious damage to crops as that reported from Skottorp (Halland) in the summer of 1916.

*Siphocoryne ligustri* Kalt. ("ligusterbladlusen,") reported for the first time in Sweden towards the end of June, 1915, on privet at Svalöv (Malmöhus district).

*Rhopalosiphum lactucae* Kalt. ("nyolktistelbladlusen"), judging by the distribution of the 55 reports received at the central office, causes serious damage in the frontier provinces between Svealand and Götaland, and in Lödermanland, Nerike and Västergötland. The southern districts, on the contrary, were almost completely immune as compared with those north of the Dal river. It is interesting that the white and red currant bushes were attacked by preference, the black varieties being hardly touched.

*Agriotes lineatus* L. ("randigasädes knäpparen") has caused considerable damage to agriculture in all districts of Sweden. In Svartingstorp (Kalm.) in 1912, some acres of sugar beets were entirely destroyed; the larvae were so abundant that 34 were collected from one root alone. In Häverö sund whole fields of oats were so severely attacked that, in many districts, they had to be re-sown. Similar occurrences were reported in Ämot and Värmland. The table given below is interesting from the point of view of the different plants' attacked.

Plants attacked	Number of attacks reported in:					Total number of attacks
	1912	1913	1914	1915	1916	
Oats . . . . .	64	38	44	53	30	229
Barley . . . . .	25	18	20	27	17	107
Wheat . . . . .	4	2	1	0	3	10
Rye . . . . .	3	1	2	8	3	17
Beet . . . . .	9	7	5	2	4	27
Potato . . . . .	6	8	7	3	5	29
Cabbage . . . . .	4	1	2	3	5	15
Turnip . . . . .	5	4	—	2	3	14
Carrot . . . . .	—	1	—	2	2	5
Onion . . . . .	1	—	—	—	2	3
Viper's grass . . . . .	—	—	—	—	1	1
Cucumber . . . . .	3	—	—	1	—	4
Salad . . . . .	2	2	—	1	—	5
Garden Strawberry . . . . .	—	—	1	—	—	1
Parsnip . . . . .	—	2	—	—	—	2
Asparagus . . . . .	1	—	—	—	—	1

Oats and barley were, therefore, most frequently attacked; cabbage, turnip, potato, beet, wheat and rye are also subject to attacks from *Agriotes*, but less frequently; the other plants may be considered as rare hosts.

*Apamea tostacea* Kb. ("gässrotflyet"), reported for the first time in Sweden at Svalöf on Gramineae in 1915.

*Dasyfolia templi* Thubg. ("fjäderborst flyet"), very rare in Sweden; in July, 1916, the larvae of this lepidopteron caused great damage to *Archangelica officinalis*, cultivated as a medicinal plant at Dals-Rostock.

*Callimorpha dominula* L. ("glansspinnaren"): the larvae of this lepidopteron, very rare in Scandinavia, caused great injury in the spring of 1914 to young elm and ash trees near Ovesholm (Kristianstadt).

*Enarmonia prunivora* Wlsh. (?) ("mindre äpplevecklaren") was noticed for the first time near Repelycke, Rännun, in November, 1915, on apples, and, on frequent occasions, in other localities. The Station has not yet been able to identify with certainty this insect, which, instead of being identical with the American *E. prunivora*, might form a native variety.

The birds reported as harmful during the period 1912-1916 were:

*Corvus cornix* L. ("kiäkan"); *C. frugilegus* L. (räkan); *C. monedula* L. ("kajan"); *Pica pica* L. ("skatan"); *Sturnus vulgaris* L. ("staren"); *Passer domesticus* L. ("gråsparven"); *Fringilla montifringilla* L. ("bergfinken"); *F. coelebs* L. ("bofinken"); *Loxia curvirostra* L. ("mindre korsnäbben"); *Pyrrhula pyrrhula* L. ("domherren"); *Turdus pilaris* L. ("snöskatan"); *T. merula* L. ("koltrosten"); *Larus canus* L. ("fiskmåsen"); *Tetrao migallus* L. ("tjädern").

Among the mammals reported as causing damage were:—

*Erinaceus europeus* L. ("sgelkotten"); *Talpa europaea* L. ("mullvaden"); *Sciurus vulgaris* L. ("äkorren") which destroys pears, apples and hazel nuts; *Microtus agrestis* L. ("akersorken"); *Arvicola terrestris* L. ("vättensorken"); *Lemmus lemmus* L. ("fjällemmel"); *Lepus timidus* L. and *L. europaeus* which gnaws the bark of fruit trees; *Alces alces* L. and *Capreolus capreolus* L., injurious to forest trees.

The attacks were frequent and serious, particularly in 1912-14, when the summers were very hot and dry; slight and less frequent in 1915 and 1916, rather wet and cold years.

The following particulars are worthy of note:—

CEREALS. — These suffered particularly from larvae of *Melolontha* sp. ("allonborren") and *Agriotes lineatus* L. throughout Sweden, but particularly in the southern districts, where, in 1912 and 1913, *Contarinia tritici* Kirby ("vetemygga") was also found in abundance in the barley and wheat fields. More or less serious damage was done by *Siphonella* (*Chlorops*) *pumilionis* Bjerk. ("kornflugan"); *Oscinella* (*Oscinis*) *frit* L. ("fritflugan"); *Hylemyia coarctata* Fall. ("rågbröddflugan"); and larvae of *Agrostis segetum* Schiff. ("sädesbröddflyet").

FODDER GRAMINEAE — *Amaurosoma* (*Cleigastrea*) *armillatum* Zett. and *A. flavipes* Fall., which lower the yield in seed of *Phleum* by 25 %.

CLOVER. — *Apion apricans* Herbst. ("Kloverspetviveln") for the seed, and a nematode, *Tylenchus devastatrix* Kuhn., for the hay.

CABBAGE and TURNIP. — *Phyllotreta* sp. ("jordlopporna"); *Plutella maculipennis* Curt. ("kålmalen"); *Eurydema oleracea* L. ("rapssugaren"); *Lygus pratensis* L. ("angstinkfiyet") in Norrland; and *Chortophila* (*Phorbia*) *brassicae* Bouché ("kålfugan").

CARROT. — *Trioza viridula* Zett. ("morotbladloppan") and *Psila rosae* L. ("morotflugan").

BEE. — *Blithophaga* (*Oiceoptoma*) *opaca* L. ("gulhåriga skinnarbaggen")

LEGUMINOSAE. — *Physopus robusta* Uzel ("vanliga arttripsen"); *Sitona lineata* L. ("årtviveln") and *Grapholihia nigricana* Stph. ("årtvecklaren").

FRUIT TREES — *Psylla mali* Schmbg ("applebladloppan"); *Psylla* sp. ("påronbladloppor"); *Aphis pomi* D. G. ("applebladlusen"), especially in the very hot summer of 1914; *Anisandrus* (*Xyleborus*, *Scolytus*, *Tomicus*) *dispar* F. ("lövvedborren"); *Phyllobius* sp. ("lövvivlar") in 1912; *Anthonomus pomorum* L. ("äppleblomviveln") in 1913-1914; *Cheimatobia brumata* L. ("frostfjäriln"); *Argyresthia conjugella* Zell. ("rönnbärsmalen") in 1916; *Malacosoma neustria* L. ("ringspinnaren").

Besides the lepidoptera already mentioned there were: *Argyroplote* (*Olethreutes*) *variagana* Hb. ("vanliga knoppvecklaren"); *Tmetocera ocellana* F. ("mindre k"); *Carpocapsa pomonella* L. ("applevecklaren"), very common; *Hyponomeuta malinellus* Zell. ("äpplespinmalen"), and *Lyonetia clerkella* L. ("clerksminerarmal").

The pear trees suffered very severely from *Contarinia pyrivora* Ril. ("pårongallmyggan"); plum trees from *Hoplocampa minuta* Christ. ("plommonstekeln"), which reduced the crop by 20 to 80 % (as at Kivik, Fjälkestad); both species were very abundant in 1912 and 1913 throughout southern Sweden.

\* BERRIES — *Pterodinea* (*Pteronius*) *ribesii* Scop ("stora krusbärsstekeln") and *Pristiphora appendiculata* Lep. ("lilla K."), on gooseberry; *Rhopalosiphum lactucae* Kalt. ("mjölkstistelbladlusen") on red currant (1915); *Anthonomus rubi* Hbst. ("hallonviveln") on strawberries and raspberries.

FOREST TREES. — *Cheimatobia boreata* Ln. ("bjork frostmätaren") and *Coleophora fuscadinella* Zell. ("bjork sackdrogarmalen"), very plentiful, especially in 1912; *Myelophilus piniperda* L. ("svarta margboren") and *M. minor* ("mindre m."); *Dendroctonus micans* Kug. ("fättekarkborren") and numerous species of the genera *Ips* and *Pityogenes*.

242 - Scale Insects (*Coccidae*) from Asia, Africa, America and Oceania. (1). — NEWSTEAD, ROBERT, in the *Bulletin of Entomological Research*, Vol. VIII, Pt. 2, pp. 125-134. London, December, 1917.

The following species are enumerated:

1) *Aspidoproctus armatus* Newst., on a tree of unknown species, San Salvador (Portuguese Congo);

2) *A. P. glaber* Lind., on the tree locally known as "mwanga", Mlanje (Nyasaland);

(1) See R. Oct., 1917, No. 977 and No. 244-244 of this Review. (Ed.)

3) *A. pertinax* Newst., on a tree known as "kalati" in the preceding locality; the same scale seems to have been observed on a wild plant at Bangalore, Lal Bagh (South India);

4) *A. tricornis* Newst., on the "mwanga" tree, Mlanje;

5) *Icerya aegyptiacum* Dougl., on young date palm, Zanzibar; this is the first record of this scale at Zanzibar;

6) *I. maxima* Newst., on tree trunk Ngamba Is., Lake Victoria (Uganda);

7) *I. seychellarum* Westw., on mango, Entebbe (Uganda);

8) *I. sulfurea* Lind., on *Eranthemum* in the preceding locality, and doubtfully on *Castilloa* at Kampala (Uganda);

9) *Stictococcus formicarius* Newst., on *Ficus* sp., Entebbe;

10) *St. multispinosus* Newst., on *Cola acuminata*, Aburi (Gold Coast); a small percentage of the females were attacked by chalcidid parasites; on *Markhamia platycalyx*, Kampala (Uganda);

11) *Sy. sjöstedti* Ckll., on cacao, Aburi;

12) *Pseudococcus citri* Risso, at Nairobi, Old Government Farm (British East Africa); on coffee, at Entebbe; on an unknown shrub, Tero Forest (Uganda);

13) *Ps. sacchari* Ckll., on rice, at Megapatan (Madras Pres.); on sugar cane at Georgetown (British Guiana);

14) *Ps. hymenocleae* Ckll., host plant not stated, at Onderstepoort, Transvaal (South Africa);

15) *Ps. virgatus* Ckll., on coffee, Nama Konkoni, Chagwe (Uganda); on cassava and sugar cane, Zanzibar; on French beans, *Jatropha Curcas* and *Colocasia*, Aburi (Gold Coast); on oleander and a creeper called "Salonica", Accra (Gold Coast); on cacao seedlings, Ibadan (Southern Nigeria);

16) *Phenacoccus insolitus* Green, on egg-plant, Saidapet (Madras);

17) *Tacchardia decorella* Mask., on *Anona muricata*, badly infested, Entebbe; Pretoria (South Africa);

18) *Asterolcanium coffeae* Newst., on coffee plants in British East Africa and in Uganda (Nakasanje, Chagwe; Banda); heavy infection; a small percentage of the specimens were infected by chalcidid parasites;

19) *A. bambusae* Bdv., on bamboo, at Aburi (Gold Coast) and at Entebbe (Uganda); also found in South Africa;

20) *Cerococcus hibisci* Green, on egg-plant, Guntur (S. India);

21) *Ceroplastodes cajani* Mask., on red gram, *Zizyphus*, *Ocimum sanctum*, Coimbatore; on wild indigo, Anantapur Dist. (S. India);

22) *Inglisia chelonioides* Green, on *Parkinsonia aculeata*, Coimbatore;

23) *I. conchiformis* Newst., on *Gliricidia maculata*, Aburi;

24) *Ceroplastes actiniformis* Green, on coconut, Coimbatore;

25) *C. africanus* Green, in South Africa; on acacia, N. E. of Lake George (Uganda);

26) *C. ceriferus* Anderson, on wild elm, Coimbatore;

27) *C. cirripediformis* Comst., on *Hura crepitans* in association

with *Lecanium* (*Akermes*) sp., Berbice (British Guiana); on *Ipomoea* sp., Georgetown;

28) *C. denudatus* Ckll., on a wild Solanaceae, Demerara (British Guiana);

29) *C. ficus* Newst., on *Ochra pulchella*, Wonderboom (South Africa); on *Anona*, Aburi;

30) *C. personatus* Newst., on *Coffea liberica*, Aburi;

31) *C. quadrilineatus* Newst., Kimi Is., Lake Victoria (Uganda);

32) *C. rubeus* Mask., on mango, Ganyon District, Chicacola (S. India); on young orange trees, Maruhubi, Zanzibar;

33) *C. ugandae* Newst., on an unknown tree, Mount Mubendi (Uganda);

34) *C. vinsonioides* Newst., on coffee, Mabira Forest (Uganda);

35) *Pulvinaria burkilli* Green, on *Zizyphus* sp., Coimbatore;

36) *P. cupaniae* Ckll., on *Ficus* sp., badly infested; on mulberry imported from U. S. A., Jamaica;

37) *P. jacksoni* Newst., on *Eranthemum bicolor*, Kampala (Uganda); on granadilla, Nairobi (British East Africa);

38) *P. psidii* Mask., on coffee badly infested, Mabira (Uganda); on the same plant at Mpumu, Chagwe (Uganda); on coffee at Kikuya (British East Africa) and on "usambyia" at Bukoba (British East Africa); on mango, Coimbatore; on guava, Koilpata (S. India);

39) *Lecanium* (*Saissetia*) *cuneiformis* Green, on *Acokanthera* sp., Mua Hills (Brit. E. Africa);

40) *L. (S.) hemisphaericum* Targ., at Limosa (Brit. E. Africa); on *Aristolochia*, Nagunga; on *Adiantum*, Entebbe; on coffee, Mabira (Uganda);

41) *L. (Coccus) hesperidum* L., on banana, near Mombasa; on lemon, Mua Hills (Brit. E. Africa);

42) *L. (S.) nigrum* Nietn., on *Lawsonia alba* and on cotton, heavily infested, Coimbatore; on coffee, Mwera (Uganda); on ornamental shrub, Government Farm, Kabete (Brit. E. Africa);

43) *L. (Eulecanium) somereni* Newst., on *Erythrina excelsa*, Nagunga (Uganda); specimen heavily parasitised;

44) *L. (Eucalymnatus) tessellatus* Sign., on Malacca apple associated with *L. wardi*, Botanic Gardens, Georgetown (British Guiana);

45) *L. (Coccus) viride* Green, on Liberian coffee, Onderneeming, Essequibo (Brit. Guiana); also observed in S. Africa;

46) *Hemilecanium imbricans* Green, on *Cedrela Toona*, heavily infested, Southern Mysore (S. India);

47) *Aspidiotus* (*Chrysomphalus*) *aurantii* Mask., on orange tree, Kabete (British E. Africa); on Mount Chirinda, Masetter (Southern Rhodesia); the insect was heavily infested by *Nectria* (?) sp.; chalcidid parasites were also present; a few specimens on *Acacia* in association with *Chionaspis capensis* Newst., at Pretoria (S. Africa); on citrus imported from India in 1913, in Jamaica; on bananas, Taveuria (Fiji);

48) *A. camelliae* Sign., on apple and rose tree, Nairobi; on trunks of black wattle, on apple and fig, Kabete (Brit. E. Africa);

- 49) *A. cyanophylli* Sign., on peach, Entebbe (Uganda) ; on banana, Taveuria (Fiji) ;
- 50) *A. cydoniae* Comst., on mango, Kabete, on Bauhinia, guava, rose shrubs, Entebbe ; on Cape lilac, Kampala (Uganda) ; on oleander, Accra (Gold Coast) ; on *Nectandra coriacea*, Jamaica ; on fig fruit and on vine, Coimbatore ; on pear, Bangalore (S. India) ; .
- 51) *A. destructor* Mask., on coconut leaves, heavily infested, but about 70 % destroyed by a small coleopterous larva, Cochin State, Kimbalengua (S. India) ; on mango in association with *Lecanium adersi* Newst., and on stems of castor oil plant, Marahubi (Zanzibar) ; on an unnamed plant, S. Africa ; on coconut palm, Mombasa (Brit. E. Africa) ; on banana, Kisubi ; on mango, guava, screw-pine and Ceara rubber, Entebbe ; on banana and *Hevea brasiliensis*, Kampala (Uganda) ; on mango, Accra and on *Pandanus*, Aburi (Gold Coast) ;
- 52) *A. (Chrysomphalus) dictyospermi* Morgan, at Fort Beaufort (S. Africa) ;
- 53) *A. (Chrys.) ficus* (Riley) Comst., on mango, Coimbatore ; on *Ficus* sp., Pemkonda (S. India) ;
- 54) *A. (Pseudaonidia) fossor* Newst., on grape vine, Georgetown (Brit. Guiana) ;
- 55) *A. orientalis* Newst., in Brit. E. Africa, on tamarind fruit, very heavily infested, at Coimbatore ; on egg-fruit, heavily infested, Guntur (S. India) ;
- 56) *A. (Chrys.) rossi* Mask., on *Eucalyptus* sp., Modderfontein (S. Africa) ;
- 57) *A. (Pseudaonidia) tesseratus* d'Emm., on *Matayba apetala*, *Nectandra coriacea*, *Trophis racemosa*, all heavily infested, Jamaica ;
- 58) *A. (Ps.) trilobitiformis* Green, in Coimbatore (S. India) ; on oleander and mango, Kampala (Uganda) ;
- 59) *A. (Chrys.) triglandulosus* Green, attached to scabs on Jack leaf, Bangalore (S. India) ;
- 60) *A. (Selenaspidus) silvaticus* Lind., on orange tree, Entebbe (Uganda) ; 50 % of the females were attacked by a parasitic fungus ;
- 61) *A. (S.) articulatus* Morgan, on citrus imported from India, Kingston, Jamaica ;
- 62) *Chionaspis (Hemichionaspis) minor* Mask., host plant not stated (cotton ?), Ibadan (S. Nigeria), on *Jatropha Curcas*, Aburi (Gold Coast) ; on willow trees, Drakensburg, Cape Province (S. Africa) ;
- 63) *Ch. dentilobis* Newst., on unnamed plant, Entebbe ; a large percentage of the females were parasitised by chalcid hymenoptera ;
- 64) *Ch. (Phenacaspis) lutea* Newst., on *Funtumia*, Aburi (Gold Coast) ;
- 65) *Fiorinia proboscidiaria* Green, on citrus imported from India, Kingston, Jamaica ;
- 66) *Parlatoria pergandei* Comst., on the same plant in the same locality ;
- 67) *P. zizyphus* Lucas, as the two preceding cases ;

68) *Ischnaspis filiformis* Doug. on *Ficus* sp. in Jamaica, on coffee, Mabira Forest, Chagwe (Uganda) ;

69) *Mytilaspis* (*Lepidosaphes*) *citricola* Pack., on sickly lime-tree, Accra (Gold Coast) ;

70) *Lepidosaphes glöverii* Pack., on croton, Entebbe (Uganda).

243 - A List of Uganda Coccidae, their Food-Plants and Natural Enemies (1). — GOWDEY, C. C., in *Bulletin of Entomological Research*, Vol. VIII. Pt. 2, pp. 187-189. London, December, 1917.

The list includes :

- 1) *Monophlebus raddoni* Westw., food plant unknown ;
- 2) *Icerya caudata* Newst., on crotons (*Codiaeum*) ;
- 3) *I. nigroareolata* Newst., on coffee and crotons ;
- 4) *I. seychellarum* Westw., on *Monodora Myristica*, *Eranthemum bicolor* and mango ;
- 5) *I. sulphurea* Lind., on *Castilloa* rubber (*Castilloa*) and guava (*Psidium Guajava*) ;
- 6) *Asterolecanium bambusae* Bdv., on bamboo ;
- 7) *A. coffeae*, Newst. on coffee ;
- 8) *Pseudococcus bromeliae* Bouché, on pine apple ;
- 9) *Ps. citri* Risso, on coffee (leaves, stems and roots), orange, lemon and cacao ; the root form is accompanied by an ant *Acropyga gowdeyi* Wheeler ;
- 10) *Ps. virgatus* Skll., on coffee ;
- 11) *Tachardia decorella* Mask., on *Anona muricata* and guava ; parasitised by *Aenasiella africa* Gir. and *Coccophagus nigropleurum* Gir., and preyed on by caterpillars of *Stathmopoda oestëdis* Meyr. ;
- 12) *T. longisetosa* Newst., on guava, *Ficus Thonningii*, and *Anona muricata* ;
- 13) *Pulvinaria jacksoni* Newst., on cotton ; parasitised by *Tetrastichus gowdeyi* Crawford ;
- 14) *Pulv. psidii* Mask., on coffee, *Funtumia elastica*, guava, tea, *Alternanthera versicolor* and *Dolichandrone platycalyx* ;
- 15) *Pulv. subterranea* Newst., on roots of *Chrysanthemum* ;
- 16) *Ceroplastes africanus* Green, on *Cajanus indicus* and *Acacia* sp. ;
- 17) *C. ceriferus* And., on coffee, *Antigonon leptopus*, orange, *Funtumia latifolia*, *Canna*, *Hibiscus*, *Agave*, croton, *Anona muricata*, tea and *Ficus Thonningii* ;
- 18) *C. conformis* Newst., on *Ficus* sp. and *Hura crepitans* ;
- 19) *C. destructor* Newst., on guava ;
- 20) *C. ficus* Newst., on *F. Thonningii* ;
- 21) *C. galeatus* Newst., on coffee and *F. Thonningii* ; parasitised by *Neomphaloidella ceroplastae* Gir., *Eurytoma galeati* Gir. and *Scutellista cyanea* Motsch. ;
- 22) *C. quadrilineatus* Newst., on *Anona muricata* and *Dolichandrone platycalyx* ;
- 23) *C. singularis* Newst., on guava ;
- 24) *C. subdenudatus* Newst., on an undetermined plant ;
- 25) *C. ugandae* Newst., on *Anona muricata* and *Acacia* sp. ;
- 26) *C. vinsonioides* Newst., on *Baikiaea Emirii*, coffee, guava and *Cajanus indicus* ;
- 27) *Inglisia castilloae* var. *theobromae* Newst., on cacao ;
- 28) *I. conchiformis* Newst., on *Hibiscus*, *A. muricata*, *Acalypha*, *Haronga madagascariensis* and guava ; preyed on by *Eublemma scitula* Ramb. ;
- 29) *Ceroplastodes gowdeyi* Newst., on *F. Thonningii* ;
- 30) *Coccus africanus* Newst., on coffee ;

(1) See also *B. Nov.-Dec.*, 1911, No. 3257 ; *B. Aug.*, 1913, No. 1010 ; *B. March*, 1914, No. 293 ; *R. Oct.*, 1917, No. 977. (*Ed.*)

- 31) *C. discrepans* Green, on tea roots ;
- 32) *C. elongatus* Sign. on *Albizzia* sp. and *Cajanus indicus* ;
- 33) *C. hesperidum* L., on orange ;
- 34) *C. setiger* Newst., on guava ;
- 35) *C. longulus* Dougl., on *Gliricidia maculata* ;
- 36) *C. signatus* Newst., on guava ;
- 37) *C. tenuivalvatus* Newst., on *Pennisetum purpureum* and *Cymbopogon citratus* ;
- 38) *C. viridis* Green, on coffee and guava ;
- 39) *Eulecanium filamentosum* Newst., on an undetermined plant ;
- 40) *E. somereni* Newst., on mulberry (*Morus*), *Tecoma stans* et *Dolichandrone platycalyx* ;
- 41) *Saussia hemisphaerica* Targ., on ferns and coffee ;
- 42) *S. nigra* Nietn., on coffee, *Ficus* sp. and *A. muricata* ;
- 43) *S. oleae* Bern., on *Chlorophora excelsa* ; parasitised by *Coccophagus sainteubevei* Gir. ;
- 44) *S. subhemisphaerica* Newst., on coffee ;
- 45) *Stictococcus coccineus* Newst., on *Acacia* sp. with *Ceroplastes subcinnabarinus* Newst. ;
- 46) *S. diversuseta* Silv., on *Hybiscus*, *Cajanus indicus*, cacao, *Croton Tiglium*, *A. muricata*, mulberry, *Artocarpus integrifolia* and *Dolichandrone platycalyx* ; preyed on by *Eublemma costimacula* Saalm. ;
- 47) *S. tormicularius* Newst., on *Ficus* sp. ;
- 48) *S. gowdeyi* Newst., on coffee and *Haronga madagascariensis* ; parasitised by *Coccophagus comperi* Gir. and *Epitetrastichus ugandensis* Gir. ;
- 49) *S. multispinosus* Newst., on *Dolichandrone platycalyx* ;
- 50) *Chionaspis cassiae* Newst., on *Cassia floribunda* ;
- 51) *C. dentilobis* Newst., on palms and *Saprum mannianum* ;
- 52) *C. funtumiæ* Newst., on *Funtumia latifolia* ;
- 53) *C. substrata* Newst., on palms ;
- 54) *Diaspis boisduvali* Sign., on *Baikiaea insignis* ;
- 55) *D. regularis* Newst., on *Chlorophora excelsa* ;
- 56) *Aulacaspis chionaspis* Green, on *S. mannianum*, *Erythrina excelsa* and *Cassia floribunda* ;
- 57) *Hemichionaspis chionaspiformis* Newst., on an undetermined plant ;
- 58) *Aspidiotus cyanophylli* Sign., on guava, palms and bananas ;
- 59) *A. cydoniae* Comst., on guava ;
- 60) *A. destructor* Sign., on banana, *Pandanus* sp., guava and mango ; preyed on by *Epilachna punctipennis* Muls. ;
- 61) *A. gowdeyi* Newst., on *Anona muricata* ;
- 62) *A. lataniae* Sign., on palms ;
- 63) *A. transparens* Green, on tea ;
- 64) *Pseudaonidia baikiaeae* Newst., on *Baikiaea* sp. ;
- 65) *Ps. trilobitiformis* Green, on oleander and mango ;
- 66) *Selenaspis articulatus* Morg., on coffee and *F. Thonningii* ;
- 67) *S. silvaticus* Lind., on orange ;
- 68) *Chrysomphalus dictyospermi* Morg., on palms, mango and rose ;
- 69) *Lepidosaphes beckii* Newm. (= *L. citricola* Pack.), on *Citrus* spp. ;
- 70) *L. gloveri* Pack., on *Citrus* and crotons ;
- 71) *Ischnaspis longirostris* on palms, bamboo and coffee ;
- 72) *Gymnaspis africana* Newst., on an undetermined plant.

244 - The Status of Introduced Coccids in South Africa in 1917 (1). — BRAIN, CHAS. K. and KELLEY, ALBERT E., in *Bulletin of Agricultural Research*, Vol. VIII, Pt. 2., pp. 181-185. London, December, 1917

The following list, compiled from data obtained up till August, 1917, during the inspection of the local nurseries, gives the species introduced and established in South Africa. Species, such as *Lecanium bituberculatum* Targ., *L. corni* Bouché, *Pulvinaria betulae* (L.) Sign., *Diaspis rosae* (Bouché), *Aspidiotus piri* Licht. and *A. ostraeformis* Curt., which having been stopped at the ports of entry, could not establish themselves in the country, are not included.

The coccids enumerated are : —

1) *Icerya purchasi* Mask., generally distributed throughout the Union but satisfactorily controlled by *Novius cardinalis*;

2) *I. seychellarum* Westw., Durban (Johannesburg, ex. Durban);

3) *Orthezia insignis* Dougl., Cape Peninsula, Port Elizabeth, East London and Natal Coast. Sporadic in Natal midlands;

4) *Pseudococcus adonidum* (L.) Westw., Cape Town, Port Elizabeth, Durban, Pietermaritzburg, Pretoria and Johannesburg. Chiefly a pot-plant pest;

5) *Ps. aurilanatus* (Mask.), Cape Town, Graaff Reinet, Durban, Pietermaritzburg, Richmond, Johannesburg and Pretoria;

6) *Ps. bromeliae* (Bouché), eastern Cape Province and Natal Coast;

7) *Ps. citri* Russo, prevalent in the Cape Peninsula, but generally confined to nurseries, where it appears to be Dr. MARCHAL's variety *Ps. citri* var. *coleorum*, as *Coleus* is chiefly attacked by it. In the same district it is very rarely found on citrus, being replaced by *Ps. fragilis* Brain; the most common species in vineyards and gardens is *Ps. capensis* Brain; similar conditions exist in Natal, but the citrus species here is *Ps. filamentosus* Ckll.; while the most common species in gardens in Durban is *Ps. virgatus* Ckll.; in Pretoria *Ps. citri* is occasionally extremely abundant on oranges, but, from the majority of citrus orchards, such as those of Rustenburg, etc., the species is apparently absent; the most common species in gardens in Pretoria is *Ps. burmerae* Brain.;

8) *Ps. filamentosus* Ckll., Bathurst, Richmond, Pietermaritzburg (*Citrus*), Pretoria (*Grevillea*);

9) *Ps. nipae* Mask, Cape Town, Graaff Reinet, Port Elizabeth, Uitenhage, Durban, Pietermaritzburg, Johannesburg and Pretoria; found only on palms in greenhouses, except at Durban, where it is occasionally found out of doors;

10) *Ps. sacchari* Ckll., Zululand, Natal Coast and Tzaneen (Transvaal),

11) *Ps. virgatus* Ckll., Durban, Pietermaritzburg and Pretoria (ex Durban);

12) *Tylococcus insolitus* (Green), East London, Kingwilliamstown, and Pietermaritzburg;

(1) See also No 242 of this Review (Ed)

13) *Eriococcus araucariae* Mask., common in the Cape and Natal, and occasionally found in Johannesburg and Pretoria ;

14) *Asterolecanium bambusae*, Bdv., Natal coast and midlands ;

15) *A. variolosum* (Ratz.), Cape Peninsula, Elsenburg, Grabouw, Paarl, Simondium, Irene, Johannesburg, Krugersdorp, Newclare and Canada Junction ;

16) *Cerococcus ornatus* Green, found on one occasion only on stems of *Dovyalis caffra* and *Calodendrum capensis* at Pietermaritzburg ;

17) *Coccus cacti* Goeze, in the Botanic Gardens, Cape Town, where it was introduced many years ago ;

18) *C. confusus capensis* Green, may usually be found where *Opuntia monacantha* is abundant, e. g. in the Cape Peninsula, Albany and surrounding districts, and occasionally in the Orange Free State ;

19) *C. indicus* Green, introduced in 1913 by the Queensland Prickly Pear Commission to destroy *Opuntia monacantha* ; it is now well established in the Cape Peninsula, Komgha, Natal and Pretoria, and was recently received from Mtunzini (Zululand) ;

20) *Lecanium hesperidum* L., widely distributed and common ;

21) *L. elongatum* Sign., Johannesburg and Pretoria ;

22) *Saissetia hemisphaerica* (Targ.), Cape Town, Grahamstown, Durban, Pietermaritzburg, Pretoria and Johannesburg (pot plants) ;

23) *S. nigra* Nietn. (*S. nigrella* King), Bayville, C. P. and Natal Coast (on *Ficus* spp. only) ;

24) *S. oleae* Bern., Cape Peninsula, Ceres, Port Elizabeth, Queenstown, Stellenbosch, Uitenhage, Fort Beaufort, Durban, Pietermaritzburg and Pretoria ;

25) *Protopulvinaria pyrififormis* Ckll., Durban, Pietermaritzburg (ex Durban) ;

26) *Aspidiotus destructor* Sign., Durban and Inchanga (uncommon) ;

27) *Aspidiotus fimbriatus* var. *capensis* Newst., Port Elizabeth (on *Cycas* only) ;

28) *A. (Diaspidiotus) forbesi* Johns., Cradock, Pietermaritzburg, Potchefstroom and Bethlehem ;

29) *A. hederac* (Vall.) Sign., widely distributed throughout the Union and common ;

30) *A. (Hemiberlesea) lataniae* Sign., generally distributed ;

31) *A. (Hemiberl.) rapax* Comst., Johannesburg, Louis Trichardt and Pretoria ;

32) *A. (Diaspidiotus) perniciosus* Comst., in most centres an attempt has been made to eradicate this insect as soon as discovered ; it has been reported from : — Estcourt, Frere, Hilton Road, Ladysmith, Moorleigh, Newcastle, Pietermaritzburg, Utrecht, Vryheid, Weenen, Winterton, Dundee and Richmond, in Natal ; Amersfoort, Benoni, Bethal, Boksburg, Boskop, Bronkhorstspuit, Cullinan, Heidelberg, Johannesburg, Middelburg, Nylstroom, Pretoria, Rayton, Scheerpoort, Standerton and Witbank, in the Transvaal ; Kroonstad and Viljoen's Drift, in the Orange Free State ;

- 33) *A. transparens* Green, Natal Coast ;
- 34) *A. (Selenaspidus) articulatus* Morgan, Durban and Pietermaritzburg ; an uncommon scale ; the most common species of *Selenaspidus* is *S. silvaticus* Ldgr. ;
- 35) *Chrysomphalus aurantii* Mask., widely distributed throughout the Union ;
- 36) *Chrys. dictyospermi* Morgan, Cape Town, East London, Kimberley, Kingwilliamstown, Durban, Pietermaritzburg, Barberton, Johannesburg, Nelspruit and Pretoria ; this species is common only in greenhouses, and though it has been found on rose and peach, it has not yet been recorded on citrus in the Union ;
- 37) *Chrys. ficus* Ashmead, common in orchards on the Natal Coast and in a few districts in the Transvaal (Warmbaths, Rustenburg and Nelspruit) ; a greenhouse pest along the Cape and Natal Coasts, and also at Queenstown, Pietermaritzburg, Johannesburg and Pretoria ;
- 38) *Chrys. rossi* Mask., Cape Town (reported but not well established here), East London, Grahamstown, Queenstown (as for Cape Town), Estcourt, Dundee, Durban, Pietermaritzburg, Johannesburg, Pretoria, Krugersdorp, Pietersburg, Bloemfontein ;
- 38\*) *Chrys. rossi* var. *greeni* n. var., East London and Durban on native trees (uncommon) ;
- 39) *Morganella maskelli* (Ckll.), established at Durban on a number of different host plants ; reported from Pietermaritzburg ; on citrus at Hillary ;
- 40) *Diaspis boisduvali* Sign., Durban, Pietermaritzburg and Pretoria (uncommon) ;
- 41) *D. biomeliae* (Kern), Natal Coast, Kingwilliamstown and Pretoria ; uncommon, chiefly in greenhouses ;
- 42) *D. echinocacti* (Bouché), Graaff Reinet and Pearston, C. P. and other places in the Karroo ;
- 43) *D. (Aulacapsis) pentagona* Targ., common in the Western Province of the Cape and in most of the other large towns in the Union ;
- 44) *Pseudaonidia trilobitiformis* Green ; Hillary (Durban) on Litchi (*Nephelium Lit-chi*) (probably ex Mauritius) ;
- 45) *Parlatoria pergandei* Comst., Cape Town, Grahamstown, Port Elizabeth, Durban, Johannesburg and Pretoria (in greenhouses) ;
- 46) *P. protius* Curt., Durban (in greenhouses, uncommon) ;
- 47) *P. zizyphi* Lucas, in several orchards near Durban ; not common ;
- 48) *Chionaspis simplex* Green. var., Durban (on bamboo) ;
- 49) *Pinnaaspis aspidistrae* Sign., common in greenhouses ;
- 50) *Fiorinia fioriniae* Targ., Cape Town, Graaf Reinet, Grahamstown, Port Elizabeth, Uitenhage, Durban, Hillary, Inchanga, Johannesburg (ex coast) ; in greenhouses ;
- 51) *Howardia biclavis* Comst., Durban ;
- 52) *H. moorsi* Doane and Ferris, Durban Botanic Gardens ;
- 53) *Lepidosaphes pinniformis* Bouché, Cape Peninsula, Port Elizabeth, Uitenhage, Stellenbosch, Somerset West, Bathurst, East London

District, Natal Coast, Cape Town, Greytown, Piet Retief, Pietermaritzburg, Barberton, Nelspruit (in citrus orchards); Cape Town, Durban, Pietermaritzburg, Uitenhage, Johannesburg (in greenhouses, chiefly on croton [*Codiaeum*] and *Murraya*);

54) *L. gloveri* Packard, Port St. Johns and in four orchards of the Cape Peninsula, Stanger and Warmbaths;

55) *Ischnaspis longirostris* Sign., East London, Port Elizabeth, Durban, Hillary (Pretoria and Johannesburg, probably ex Durban), occurs on a number of ornamental plants; at Warmbaths on citrus.

245 - The Fluted Scale (*Icerya purchasi*). — SPEYER, F. R., in *Department of Agriculture, Ceylon, Leaflet No. 3*. Colombo, Ceylon, March, 1917.

So far as is known India is still free from attacks of this dreaded insect. The island of Ceylon was also considered to be immune till, in December, 1915, the insect was discovered on *Acacia decurrens* on an estate in the Agradipatnas (Central Province). It was, immediately after, reported from another estate in the same district, again on *A. decurrens*, and was found at Paradeniya on numerous specimens of *Casuarina*, one of which was seriously attacked. In August, 1916, an *Acacia* forest in Ambawela was attacked by large numbers, which, in October, were exceeded on the estates in the Agradipatnas. The insect was also found on *A. dealbata*. It was next noticed that acacia plants served as hosts to the scale in the districts of Galaha and Upper Hewaheta, and two females were found on a citrus in the first of these districts. Reports from Kandy show that, though other plants may be attacked, acacia is the centre of infection.

Apart from the damage which may be done to fruit trees and the temporary weakening of the acacias, as a result of the holes made by the insect, there are other plants in the island which it is important to protect from its attacks.

Although controlled by a fungus, *Cephalosporium*, during the north-east monsoon in the districts of Ambawela, Hewaheta and Galaha, and, it seems, before this monsoon in the Agradipatnas, the insect increases very greatly during the other periods. There are native lady-birds which feed on the scale at Paradeniya and at Ambawela, but, at present, they are few in number. The chances of its spontaneous natural extermination are small, and for some time yet an increase is to be expected.

To control the pest before it touches economic products, a full knowledge of its distribution is urgently required. It may still be sufficiently localised for radical extermination to be possible. If it be more widely distributed, radical extermination might be used in the worst centres, while lady-birds imported from South Africa or Australia could be distributed to all outlying localities with a view, at least, of keeping the scale within bounds.

246 - Observations on *Lepidiota frenchi* Black, A Sugar Cane Pest in Queensland (1). — JARVIS, EDMUND, in *Queensland Bureau of Sugar Experiment Stations, Division of Entomology, Bulletin No. 5*, pp. 1-14, 1 pl. Brisbane, 1917.

Although rather less injurious to sugar cane than the grey-back cockchafer (*Lepidiota albohirta* Water) (2), *L. frenchi* Black may, from an

INSECTS, ETC.,  
INJURIOUS  
TO VARIOUS  
CROPS

(1) See also B. August, 1915, No. 874; R. Sept., 1916, No. 1048. — (2) See also R. Dec., 1916, No. 1343. (Ed.)

economic point of view, be considered as holding second place among the Scarabaeidae which attack this crop in northern Queensland.

The coleopteron, which normally lives at the expense of the root system of the native cereals and other herbaceous plants, shows a marked preference for sugar cane. An invasion of the insect, the importance of which is worthy of note, was reported at Meringa (District of Cairns) in April, 1917. While ploughing red volcanic soil there were collected from 50 chains of furrow, within a few hours only, 186 larvae of the second stage, representing 2 418 larvae per acre, *i. e.* an average of 0.85 per stool of cane.

Considering the affinity between *L. franchi* and *L. abohiria*, the excessive abundance of the insect in question, its varied diet, its frequent appearance in sugar cane plantations and its preference for this plant, the author has collected in his paper the observations made up to the present on the life cycle of the insect and its habits.

247 - Common Pests of Fruit Trees in Ontario, Canada. — CAESAR, LAWSON, in Ontario Department of Agriculture, Ontario Agricultural College, Bulletin 250, pp. 1-55, figs. Toronto, Ontario, July, 1917.,

No attempt is made in this bulletin to discuss all the insect pests of fruit trees, but only the most common and the most to be dreaded economically. The description of each insect is followed by information concerning its biology and the most efficacious means of control.

APPLE TREE. — Codling moth (*Carpocapsa pomonella* L.); Lesser apple-worm (*Enarmonia prunivora* Walsh); Apple maggot (*Rhagoletis pomonella* Walsh); Fruit-tree leaf-roller (*Tortrix argyrospila* Walker; San José scale (*Aspidiotus perniciosus* Comstock); Oyster-shell scale (*Lepidosaphes ulmi* Bouché); European grain aphid (*Aphis avenae*); Rosy aphid (*A. [sorbi] malifoliae*); Apple leaf-aphid (*A. pomi*); Woolly aphid (*Eriosoma lanigera* Hausmann); Mirids or leaf-bugs (*Heterocordylus malinus* Reuter, *Lygidea mendax* Reuter, *Neurocolpus nubilus* Say and *Paracalocoris colon* Say); Apple tent-caterpillar (*Malacosoma americana* Fabricius); Forest tent-caterpillar (*M. disstria* Hubner); Fall canker-worm (*Alsophila pomataria* Harris); Spring canker-worm (*Paleacrita vernata* Peck); Bud-moth (*Tmetocera ocellana* Schiffermüller); Cigar case-bearer (*Coleophora fletcherella* Fernald); Pistol case-bearer (*C. malivorella* Riley); Green fruit-worms (*Xylina* spp.); White-marked tussock-moth (*Hemerocampa leucostigma* Smith and Abbott); Fall web-worm (*Hyphantria cunea* Drury); Buffalo tree-hopper (*Ceresa bubalus* Fabricius); Round-headed apple-tree borer (*Saperda candida* Fab.); Plum curculio (*Conotrachelus nemophar* Herbst.); Red spider (*Tetranychus pilosus* [*T. mytilaspidis* Riley?]) Fruit-tree bark-beetle or shot-hole borer (*Eccoptogaster rugulosus* Ratzeburg).

PEAR TREE. — Pear psylla (*Psylla pyricola* Forester); Pear slug (*Eriocampoides limacina* Retzius); Pear-leaf blister-mite (*Eriophyes pyri* Pagenstecher); *Carpocapsa pomonella*; *Xylina* spp.; *Tmetocera ocellana*; *Coleophora fletcherella*; *Tortrix argyrospila*; *Hemerocampa leucostigma*; *Hyphantria cunea*; *Malacosoma americana*; *M. disstria*; *Aspidiotus perniciosus*; *Lepidosaphes ulmi*; *Eccoptogaster rugulosus*.

PLUM TREE. — *Conotrachelus nenuphar*; *Tetranychus pilosus* (*T. mytilaspidis* ?); *Xylina* sp.; *Tmetocera ocellana*; *Coleophora fletcherella*; *Tortrix argyrospila*; *Alsophila pometaria*; *Paleacrita vernata*; *Hemerocampa leucostigma*; *Malacosoma americana*; *M. disstria*; *Ceresa bubalus*; *Aspidiotus perniciosus*; *Lepidosaphes ulmi*.

CHERRY TREE. — Cherry fruit-flies (*Rhagoletis cingulata* Loew and *R. fausta* Osten Sacken); Cherry aphid (*Myzus cerasi* Fabricius); *Eccoptogaster rugulosus*; *Tmetocera ocellana*; *Tortrix argyrospila*; *Alsophila pometaria*; *Paleacrita vernata*; *Malacosoma americana*; *Ceresa bubalus*; *Aspidiotus perniciosus*; *Eriocampoides limacina*; *Conotrachelus nenuphar*.

PEACH TREE. — Peach-tree borer (*Sanninoidea exitiosa* Say); *Sesia pictipes* Grote and Robinson; *Xylina* spp.; *Tmetocera ocellana*; *Malacosoma americana*; *M. disstria*; *Aspidiotus perniciosus*; *Conotrachelus nenuphar*; *Eccoptogaster rugulosus*.

248 - **Three-Lined Fig-Tree Borer.** — HORTON, J. R., in the *Journal of Agricultural Research*, Vol. XI, No. 8, pp. 371-382, pl. 35-37. Washington, D. C., November 19, 1917.

The adult three-lined fig-tree borer (*Ptychodes trilineatus* L.) does considerable damage to fig-trees (*Ficus Carica*) in the south of the United States from Florida to Houston, Texas, and from South Carolina to the Gulf. It has also been reported from parts of Mexico, British Honduras, Nicaragua, Costa Rica, Guatemala, Panama, the West Indies, Columbia, Venezuela, and Tahiti.

The adult causes some injury by feeding on the fruit, leaves and bark of the trees, and by ovipositing in the bark, but the greatest amount of damage is done by the larva. The larva mines into the larger branches and trunks of the trees and feeds upon the wood for a period varying from three months to a year. The insect lives both in dry and in green wood, and specimens have lived for two or three weeks in wood other than fig. It appears to prefer partly dead wood which has lost some of its sap to healthy green wood, and, therefore, chiefly attacks trees or branches which are injured or diseased.

A detailed description of the life-cycle and habits of the borer is given.

As the adult does not, as a rule, lay its eggs in the perfectly sound limbs or trunks of the healthy trees, it is most important to keep the trees in the healthiest condition possible. The larger branches and trunk are the parts particularly susceptible to attack. Bruising the bark, breaking the limbs, and all kinds of disease should be carefully guarded against. If a branch be accidentally broken it should be cut off at its base immediately and the wound painted several times with a mixture of coal-tar and creosote. Infested branches should be cut off and burnt, as the borers will complete their development even in perfectly dead wood, and, later, attack other trees. Prunings should be destroyed and never left in or near the orchard. Frozen branches should be cut off, diseased or bruised bark removed, and the wounds suitably painted.

Trees heavily infested in the bark, which can no longer be saved,

should be cut down, and every scrap burnt. The same should be done with badly damaged or dying trees, and the shoots which spring up from the roots of old fig trees.

In certain cases the eggs may be dug out with a knife or an awl; in this case it is necessary to be able to recognise the egg punctures and eggs. In small orchards ovipositing may be largely prevented by protecting the trunk and larger branches with wire-netting, which should be left on all the year. In some cases the borers may be killed by injecting carbon bisulphide into the tunnels and plugging the openings with putty, but this method is impracticable when infestation is severe and well advanced.

249 - *Oscinosoma discretum*, a Dipteran Observed in the Fruit of Wild Figs, in Italy. — SILVESTRI, F., in *Bollettino del Laboratorio di Zoologia generale e agraria della R. Scuola superiore d'Agricoltura in Portici*, Vol. XII, pp. 147-151, figs. 1-1X. Portici, 1917.

While studying another dipteran — *Lonchaea aristella* Beck. — the author frequently found in the flowers of the wild fig tree, eggs and larvae of *Oscinosoma discretum* Bezzi in litt. (fam. Chloropidae). He describes the life history of this species, observed hitherto near Portici and Resina (province of Naples), so that it may be distinguished from *L. aristella* and the larvae of other diptera attacking the fruit of the wild fig.

The insect lays its eggs under the scales of the eye of the ripe flowers and, though rarely, in the ripe second-figs, by placing them horizontally as does *L. aristella*. In one fruit may be found numerous eggs — more than 100 — of *O. discretum* alone or together with those of *L. aristella*. The newly-hatched larvae penetrate to the inside of the fruit and feed on the remains of the decomposing flowers and on the parenchyma of the wall of the fruit itself. When fully developed they leave the flower, which has usually fallen to the ground and pupate a few inches below the surface. Like *L. aristella* this species takes about 20 days to develop from the egg to the adult stage.

Although the eggs and larvae of *O. discretum* were abundant in the ripe flowers in June and July, 1917, and all the pupae produced perfect insects at the end of July or beginning of August, neither the eggs nor larvae of the species were found in many figs of the wild tree, during the rest of August. It was only on the 4th. September that the author found a few eggs of *O. discretum* in ripe second figs picked near Resina, whereas, in the same second figs, larvae of *L. aristella* were present in enormous quantities. So far, the author has never found eggs of *O. discretum* in figs of the good varieties, and, having found the eggs and larvae of the dipteran only in the flowers and ripe second figs, he doubts whether this variety lives normally in any other way. This must be settled by later studies; for the moment it is certain that *O. discretum* exists in abundance in the ripe flowers in June and July.

AGRICULTURAL INTELLIGENCE

GENERAL INFORMATION.

250 — **The Agricultural Wealth of the New Hebrides.** — LARGBEAU, T. (President of the French Agricultural Syndicate of the New-Hebrides), in the *Revue agricole, Organ de la Chambre d'Agriculture de la Nouvelle Calédonie*, No. 54, pp. 31-52. Noumea, 1917.

DEVELOPMENT  
OF  
AGRICULTURE  
IN DIFFERENT  
COUNTRIES

The chief crops of the New Hebrides are *coffee*, *cacao*, *copra*, *cotton* and *maize*. Under present conditions these are the only remunerative ones. *Kola*, *vanilla*, *pepper*, *spices* of all kinds, *manioc*, the most varied *textiles*, *rice*, *sorghum*, *banana*, etc., yield as good crops as elsewhere, but the quality of the labour and economic reasons, do not, for the moment, allow these to be grown advantageously.

This, however, does not apply to *coffee* of which the hardy species recently imported from the Congo through the Botanical Garden of Java, give great promise.

*Cacao*, of which large plantations were formed when hemileia made its appearance in 1913, has given remarkable results. The cacao of the New Hebrides is in no way inferior in theobromine and butter content to any of the best varieties on the European markets.

For the moment *copra* holds the first place in commercial value among the products sent from the New Hebrides.

*Cotton* gives excellent results both in quality and yield, but growers seem to be taking less and less interest in this crop which requires much labour for picking. Certain estates which were under favourable conditions in this respect have made very large profits.

*Maize*, although satisfactory, will never be grown to any but a limited extent on account of heavy freight and the few markets available.

*Sandal-wood* grows wild in certain parts of the islands. For four years it has been subjected to intensive cutting, which, in view of the impossi-

bility of regulation, shows it will be ruined before long. There are other valuable woods which are not exploited owing to lack of labour and capital.

The following table shows the comparative value of the agricultural products exported from the New Hebrides from 1914-1916.

	1914			1915			1916		
	lbs.	£.	s. d.	lbs.	£.	s. d.	lbs.	£.	s. d.
Cacao . . . .	97 231	3107.17.	5	173 652	5621. 8.	2	9504 774	19063.17.	5
Coffee . . . .	331 841	10742. 5.10		833 851	26994. 4. 7		3594 079	19231. 8. 7	
Copra . . . .	7 349 185	66085.10. 8		9 017 252	81082.13.11		3 184 332	82600. 8. 3	
Cotton . . . .	1 524 036	13701. 4. 3		3 486 131	31347.17. 5		862 302	34730. 7.10	
Maize . . . .	1 025 235	22593 11. 0		3 333 965	8994. 8. 4		412 756	7582. 8. 9	
Sandal-wood .	225 869	2813. 9. 0		236 339	2989.16. 0		301 790	4345.10. 2	
Total.	—	119076.14.11		—	157032. 8. 5		—	167554. 1. 0	

Almost all the exports rise from year to year, and there will be a considerable increase in 1917.

It should be noted that all these results were obtained in spite of the lack of agricultural instruction, with most primitive tools and without the aid of agriculturists and chemists as is the case in other countries. Under present conditions, if there is sufficient labour, it may be estimated that, in 1920, the products will amount to: — 1 500 metric tons of cacao, 6 000 of copra, 1 000 of coffee, 3 000 of cotton and 2 000 of maize, without counting other produce, such as shells and costly woods.

#### RURAL HYGIENE

251 — *Gambusia affinis*, a Small Fish Very Useful for the Destruction of Mosquito Larvae. — RAVERET-WATTEL, C., in the *Bulletin de la Société Nationale d'Acclimatation de France*, Year L, XIV, No. 12, pp. 445-451. Paris, December, 1917.

*Gambusia affinis* Baird and Girard is a very small fish (the largest specimens rarely attain a length of 5 cm.) belonging to the family Cyprinodontidae, which closely resemble Cyprinidae in outward appearance, but are differentiated by several characters, notably the presence of teeth; many of them are ovoviviparous, as is the genus *Gambusia* (1).

The Gambusias are of no value as food, but are of great utility as their food consists almost wholly in mosquito larvae, of which they destroy great numbers. They are the best fish as destroyers of mosquitoes as they live at the surface of the water (whence the name of "top minnows", given in the United States) and they can live in water so shallow as to be uninhabitable for other species; large numbers of this fish are often found in ponds where the mud is, at times, only covered by 3 cm. of water.

The fish breed easily, on account of their hardiness and the fact that, as they are born in an advanced state of development, they are less exposed to various dangers. Experiments made in New Jersey have shown that not only are they easy to breed, but they constitute a hitherto neglected means for controlling mosquitoes wherever the water is sufficiently warm.

(1) The name of *Gambusia* is derived from "Gambusina", a Cuban word meaning a very small or worthless object. (Author).

252 - **The Digestibility of the Dasheen.** — LANGWORTHY, C. F. and HOLMES, A. D., in U. S. Department of Agriculture, *Bulletin* No. 612, pp. 11. Washington, November 8, 1917.

The dasheen and other varieties of the taro (*Colocasia esculenta*) was till recently very little known in the United States, but of late the Department of Agriculture has given much attention to the selection of varieties suited to warm districts where the potato does not do well.

The edible part consists of a large central root, which may weigh from 1 to 5 lbs., or even more, and by numerous small tubers about the size of sweet potatoes. The dasheen may be cooked in several ways, like the potato, and has a pleasant flavour. As the literature on the subject gives no information on the digestibility of this food, the Department of Agriculture carried out feeding experiments on strong, healthy men on a simple, but mixed diet. The results were : —

*Digestibility of the Dasheen.*

	Protein	Fat	Carbo- hydrates	Ash
Unripe roots and tubers (average of 6 experiments). . . . .	79.9 %	96.2 %	97.5 %	79.4 %
Ripe roots and tubers (average of 10 experiments). . . . .	80.8	96.1	97.6 %	78.4

The average amount of food eaten daily per subject in all the experiments was 1733.4 gm., giving 1313.6 gm. of water, 41.2 gm. of protein, 129.4 gm. of fat, 230.6 gm. of carbohydrates and 18.6 gm. of ash. The amount of dasheen eaten per man per day varied from 376 gm. to 731 gm. with an average of 547 gm. In no case did such large quantities of dasheen cause physiological disturbances. The results show that the carbohydrates of dasheen, which form one of its principal constituents, have a digestibility which may be compared with that of the potato (99.0 % according to BRYANT and MILLER, 92.4 % according to RUBNER, 99.6 % according to CONSTANTINIDI). There is no perceptible difference between the digestibility of ripe and unripe dasheen. In conclusion, it may be said that dasheen forms an excellent food.

253 - **Hygienic Disadvantages of Using Lime in Breadmaking.** — See No. 344 of this *Review*.

254 - **Studies and Investigations of the Imperial Institute, London (1).** — *Bulletin of the Imperial Institute*, Vol. XV, No. 2, pp. 177-184, 198-270. London, April-June, 1917.

PRODUCTION AND USES OF RICE. — An article on the cultivation and preparation of rice was published in previous numbers of the *Bulletin of the Imperial Institute* (Vol. XI, p. 634, 1913; Vol. XII, p. 85, 1914), in which the varieties of rice, methods of cultivation and preparation, pests and diseases, were described and an account given of the production of this cereal in the British Empire. The article under review deals with the production

EXPERIMENTAL  
AND  
ANALYTICAL  
WORK

(1) See also R. January, 1918, No. 5. (*Ed.*)

and commercial movement of rice, especially in the British Empire, and the use of rice and its derivatives.

The production of rice, as shown by official estimates, for nearly all the rice-growing countries is given in the appended table. The chief omission is China, for which figures are not available.

*World's production of rice.*

Country	Production (cleaned rice) tons	Country	Production (cleaned rice) tons

\* Exporting countries, in which production exceeds consumption.

\*\*Importing countries, in which consumption exceeds production. It is doubtful to which category the countries without any mark belong.

**TAPIOCA STARCH FROM RHODESIA.** — Cassava or manioc (*Manihot utilissima*), from the roots of which tapioca and tapioca starch are prepared, has been grown for several years at the Agricultural Experiment Station, Salisbury, Rhodesia. The plant does very well there. The roots when fed to stock produced no ill effect. Some of the starch, prepared experimentally at Salisbury was sent to the Imperial Institute to be examined; it gave the following analysis: —

Moisture 14.4 %; proteins 0.1 %; fat 0.15 %; starch 82.8 %; ash 0.2 %; fibre and matter soluble in water, nil.

A firm of importers stated it to be of good quality and valued it at £ 28 per ton, ex quay Liverpool. Another firm considered it of medium quality and valued it at £ 20 to £ 25 per ton, delivered in Dundee.

**THE LIME FRUIT IN NIGERIA.** — The lime tree (*Citrus medica* var. *acida*) occurs in most parts of British West Africa, and in some places has become naturalised. The fruit is used to some extent locally for the preparation of lime juice, but there is no export trade in either the fruit or its products.

The possibility of utilising the fruit has been investigated by the Government Chemist at Lagos, who sent to the Imperial Institute for examination fresh fruit, distilled oil of limes, and a sample of citrate of lime. The fruit was found rather small ( $1\frac{3}{8}$  to  $1\frac{5}{8}$  inches in diameter), but sound and of good quality. There is a very small demand for them on the English market. Analysis showed them to contain : —

Percentage of juice to fruit . . . . .	57.4
Total solids in juice . . . . .	10.6 gm. per 100 cc.
Citric acid in juice . . . . .	8.2 gm. per 100 cc.
Purity of juice (ratio of acid to total solids) . .	77.0
Percentage of citric acid in entire fruit . . . . .	4.4

To prepare the oil with the ripe fruit, the juice, skin and pulp are distilled in steam separately and the distillates mixed. The average yield was 0.17 % of the whole fruit. The oil, of a pleasant odour and good quality, was similar in character to the Italian oil distilled from *Citrus Limetta* : —

Specific gravity at 15° C., 0.8946; optical rotation at 20° C., + 34°4'; refractive index at 21° C., 1.4815.

The citrate of lime was prepared from the concentrated lime-juice in the ordinary way. The yield of juice varied from 6 to 7 fluid oz. per lb. of fruit, and the yield of citrate from 0.55 to 0.6 oz. per lb. of fruit. The sample examined contained : —

Moisture 4.9 %; citric acid 70.6 %; calcium carbonate 1 %.

It was stated to be of excellent quality and certain of a ready sale.

**PISTACHIO NUTS AND THEIR CULTIVATION.** — The pistachio tree (*Pistacia vera*, Linn.) a native of Syria and Persia, is cultivated throughout the sub-tropical Mediterranean region, as well as in the Caucasus and in several parts of western Asia. Its climatic requirements are similar to those of the olive. In its original habitat it may occur at altitudes of 3 000 feet. It prefers light soil, but will grow well in any that is not too damp. It is resistant to wind and can withstand a few degrees of frost in winter, but requires a high summer temperature in order to fruit plentifully. It is commonly held to yield a good harvest only in alternate years. It gives the best results in Tunis, and especially in Sicily, where, in view of the rapidity of its growth, it might be much more widely cultivated than it is. It may be propagated by sowing, grafting or budding. Budding is the most common method, as by this means the tree may bear fruit after 2 or 3 years. Plants grown from seed only bear fruit after 6 or 8 years, and, as the tree is a dioecious Anacardiaceae, it is impossible to foresee whether it will be productive (female). About  $\frac{1}{10}$  of the plants are male. Grafting is carried out on other species of *Pistacia*, giving more resistant trees which

do well where *P. vera* from seed would not succeed ; thus, grafted on *P. Terebinthus* (grown from seed), it will give plants that will bear fruit in Central France. Once established, the pistachio needs little attention, but fertilisation must be assured. As a rule one male tree is required to every 4 or 6 female trees, and the distance between a male and female tree should not exceed 20 yards. A male graft may be grown on a female tree, or buds from both kinds of trees inserted in the same stock.

It is probable that the cultivation of the pistachio could be considerably extended. It grows readily in Cyprus, where it is commonly budded or grafted on *P. Terebinthus* and *P. Lentiscus* but does not produce well owing to the scarcity of male plants. In the East the fact that the plant is dioecious is not sufficiently appreciated. The tree could probably be grown in India, and its cultivation might be successful in the southern hemisphere, for instance in Australia and South Africa.

Pistachio nuts are an important article of commerce ; the imports into France (mainly from Russia and Turkey) in 1913, were 4 280 cwt., and the exports were 3 517 cwt., 1 982 of which went to the United States, the total value being £ 42 888. The composition of the kernel is : —

Water 7.4 % ; crude proteins 22.7 % ; fat 51.1 % ; carbohydrates 13.0 % ; cellulose 2.5 % ; ash 3.3 % ; food units 197.5.

The oil extracted from the kernels has the following constants : —

Specific gravity at 15° C. 0.9185 ; saponification value 191.0-191.6 ; iodine value 86.8-87.8 % ; solidifying point of fatty acids 13-14° C.

**WAX FROM *Ceroxylon andicolum*.** — This palm occurs only in western tropical South America, where it is very abundant. The wax, obtained from the leaves, is used in Colombia for making candles, but has not yet been exported. A sample of fine powdered wax of a pale straw colour examined at the Imperial Institute, and the wax obtained after purification, showed the following composition and characters : —

Moisture 1.5 % ; ash 0.6 % ; wax 92.0 % ; dirt (matter insoluble in carbon tetrachloride) 6.5 % ; specific gravity at 15° C. 1.018 ; acid value 19.8 ; saponification value 73.7-104.4 ; iodine value 32.8 % ; melting point (open tube method) 93° C.

The purified wax is similar in character to carnauba wax (*Copernicia cerifera*), which is obtained chiefly from Brazil, and the candelilla wax (*Euphorbia* sp.), imported from Mexico, but has a higher melting point (that of the two others is 84° C. and 70-72° C. respectively). It would be readily saleable at about the same price as these two waxes, which before the war, fetched from £ 5 to £ 9 per cwt. in the United Kingdom.

The wax must be purified before export. The following method is recommended by the Imperial Institute. The crude wax-dust is placed in a canvas or calico bag and immersed in boiling water, the bag being weighted to keep it below the surface. The melted wax rises to the surface, where it is allowed to cool. When cold, the wax is powdered and dried. It is then melted at a gentle heat (not more than 110° C. and not longer than necessary), allowed to solidify and the lower dark layer cut away, and either sold separately or repurified with the next batch.

- 255 — **Electrical Stimulation of Crops.** — BIRKS, L. and DAVIS, O' D., in *The Journal of Agriculture, New Zealand Department of Agriculture, Industries and Commerce*, Vol. XV, No. 4, pp. 185-190, 2 figs. Wellington, October, 1917.

New Zealand possesses large supplies of hydro-electric power and is in a particularly favourable position to apply this power to cultivation. Preliminary experiments have been made at Christchurch. The first was carried out in a greenhouse 80 feet  $\times$  30 feet in which 1 400 tomato-plants were set out. The house was fitted with lamps, hung 2 feet from the ground, which were kept alight from 9 p. m. till 5 a. m. As the plants grew the lamps were raised, until they were finally covered by the tops of the plants. At the beginning of the experiments the steam-pipes had gone out of order and many plants had been injured by a severe frost before the heating apparatus could be repaired. The plants recovered rapidly and gave a very heavy crop, ripening relatively earlier than those of another glasshouse, where the plants, which were not attacked by frost, were grown under similar conditions but without lighting at night.

A second experiment was carried out to test the possibility of protecting fruit trees against frost by means of 250-watt radiator lamps suspended in the centre of the tree, near the fork, and turned on during the nights when frost was to be feared. Three rows of 8 trees each were used for the experiment, one of pear-trees and two of mixed apples. The radius of action of the heat of the lamp was found to be approximately 1 ft. below the lamp, 4 ft. above it, and 3 ft. all round it horizontally. There were many frosts, two of which were very severe. Electric heating did not appear to have any effect on the pear-trees, but the apple-trees gave a heavier crop and ripened fully a fortnight earlier than those which were not heated by electricity.

The cost of installing electricity for stimulating crops in glasshouses is not prohibitive, working out at about 10 to 20 % of the actual present capital and interest and depreciation cost of the glasshouse. The use of electricity for stimulating plant growth would be very valuable, especially for early crops.

## CROPS AND CULTIVATION.

- 256 — **The Problem of Agricultural Meteorology** (1). — AZZI, G., in *Bollettino del Ministero di Agricoltura, Industria e Commercio*, Series B., pp. 1-10. Rome, 1916, and in *Bollettino bimensuale della Società Meteorologica Italiana*, Series III, Vol. XXXV, Nos. 6-7-8, pp. 25-32; Nos. 9-10, pp. 39-42. Turin, 1917.

AGRICULTURAL  
METEOROLOGY

THE PRINCIPLES NECESSARY TO THE SOLUTION OF PROBLEMS OF AGRICULTURAL METEOROLOGY. Among the variations in the yields of crops those caused by atmospheric changes hold the first place. These changes are of

(1) In March, 1911, the general Meeting of the\*Delegates of the States adhering to the International Institute of Agriculture received favourably the proposal of Mr. L. OUIS DOP (French Delegate and Vice-President of the Institute) with regard to the international organisation of agricultural meteorology, and decided to send officially the report to the President of the International Committee of Meteorology.

In September, 1912, at a meeting of the Central Meteorological Bureau, Mr SHAW, Presi-

far greater importance than those due, for example, to the use of fertilisers, to cultivation, etc. For this reason studies aiming at reducing the damage done by meteorological factors deserve the greatest attention. The author has drawn up a very detailed scheme which permits the damage caused by weather to be reduced with certainty, by favouring a more rational adaptation of the various crops to the climates of the different districts.

Three principles are required for the solution of problems of agricultural meteorology: — 1) a knowledge of the critical period; 2) phenological maps; 3) weather charts.

*Critical period.* — From germination to harvest the plant undergoes great modifications which change its form and structure, so that its requirements, even with regard to the various meteorological factors, vary during the growing period.

The critical period with regard to "rain" is the interval, more or less long, of the growing period during which the plant has an absolute need of a certain minimum quantity of water. If, during the critical period, the total rainfall is below the minimum required for the normal growth of the plant, the harvest will be poor, even though there be abundant rain during the rest of the growing period, and, inversely, if during the critical period, the needs of the plant are satisfied, the harvest will be plentiful, even though the rainfall during the rest of the growing period be scarce and badly distributed.

The critical period of cereals falls during the twenty days preceding earing. If, at this moment, there is not sufficient rain to keep the moisture of the soil above a certain limit, the grain harvest will be seriously compromised.

What has been said for rain may be repeated for all the other factors. A plant may, therefore, have more than one critical period, those of rain, frost, temperature, clouds, etc. One or all of these periods may assert itself and assume importance according to the local conditions of the climate.

The necessity of a detailed physiological and meteorological examination is thus obvious when it is desired to ascertain with exactitude in each district the cause of a failure in the crops and the requisite remedies.

*Phenological maps.* — In a certain number of stations in different parts of Italy the average date is calculated when the peach, for example, flowers, and the data obtained is marked on the map at points corresponding to the various stations. All the districts, in which flowering occurs in the same decade are included in one zone and the various zones marked in different colours. This gives the phenological map of the flowering of the peach tree.

The critical periods referred to above always coincide with some phase of growth (flowering, earing, etc.), that is to say, to a moment when the

ment of the International Committee of Meteorology, formed a commission of 5 members who drew up a scheme of work to be submitted to the International Committee of Meteorology. The commission, on which were placed other technical specialists, should have met in December, 1914. The war interrupted its work. (See B. Dec. 1912, No. 1605).

plant undergoes great modifications which make it very sensitive to the lack of rain or to other unfavourable meteorological phenomena. Thus, at the flowering stage of fruit trees, a drop in the temperature, which at other moments of growth would have no effect, suffices to compromise seriously the fruit crop.

If the average date of the different stages in the growth of a plant (leafing, flowering, ripening of the fruit) are known, it is possible to determine the period of the year during which the plant is particularly sensitive to the harmful action of certain phenomena, or particularly exacting with regard to humidity, temperature, etc. Thus, if the average date of flowering of the peach tree at a station A is February 5, the critical period of that tree with respect to frost will be the first 10 days of February. The phenological maps, then, make it possible to determine the critical period. For each variety grown there should be as many phenological maps as there are important stages of growth in relation to weather. For cereals these are: 1) germination; 2) earing; 3) flowering; 4) ripening of the grain.

*Weather charts.* — In 1910, in the province of Bologna, there was no rain during the 20 days preceding earing, which took place on May 15; and the harvest was below the average by about  $9\frac{1}{2}$  cwt. per acre. On the other hand, there was abundant rain during the first half of April. By earlier sowing and the use of an earlier variety it would have been possible to bring the earing stage to April 25-30 so as to make the critical moisture period coincide with a more favourable meteorological moment. For this, however, it would be necessary to know at the end of October what the weather could be in spring. It is not possible to make a good weather forecast for more than 24 hours, or, at a maximum, 48; *the crops cannot, therefore, be adapted to the weather.* If, however, it is impossible to foretell in autumn what will be the atmospheric variations at Bologna and Sciacca (Sicily) during the second half of April, there is no doubt that drought is much more frequent and likely to occur during this period at Sciacca than at Bologna.

*If the crops cannot be adapted to the weather, it is possible to adapt them to the climate, which represents the average weather and is expressed by a series of percentages of probability: — probability of frost, drought, storms, clouds, etc.*

The author applies the term "dry decade" to a period of 10 days where the total rainfall does not exceed 5 mm. By calculating for a certain number of districts over a long period (a minimum of 20 years) the number of times a certain decade has been dry, and comparing these figures to 100, the probability of drought for this decade will be obtained. Assuming that, at the station A, the 2nd. decade of July has been dry 15 times in 20 years, the probability of drought during this period at A will be 75 %.

This percentage is marked on a map at the points corresponding to the different stations. All the points where the probability of drought is from 70 to 100 % form one zone, in which drought is certain; those where this probability is from 30 to 70 % form a second zone, and those where it is from 0 to 30 % form a third zone where drought is very rare during the

decade under consideration. The zones are marked in different colours. In this way a chart will be obtained for each decade which will enable the distribution of *drought* for a given period to be ascertained at a glance. Similar charts would be made for *frost* ("cold decade"), *clouds*, *storms and mist*.

AGRICULTURAL METEOROLOGY STATIONS. — The critical period of a plant with regard to a meteorological factor may be restricted to one or two decades. Taking as example the Agricultural School of Imola where agricultural observations are made, and the nearest meteorological observatory that of Bologna, about 20 miles away, it may well happen that, during the critical period of moisture for wheat, a shower may fall at Bologna while the drought continues at Imola, or vice versa. A comparison between the phenological and biological data registered at the school and the meteorological data of the observatory may, therefore, lead to erroneous conclusions. It is necessary that the biological and meteorological observations be carried out at the same time and place: — the agricultural meteorology station.

The author considers that an entirely new scheme is unnecessary, more especially as in no case should a new station of agricultural meteorology be built, use being made of those stations and agricultural schools already existing by supplying them with building, technical staff and experimental fields. Each station should have the following instruments: —

- 1) rain-gauge;
- 2) hygroscope;
- 3) maximum and minimum thermometers;
- 4) earth thermometers;
- 5) bore for taking samples of soil at different depths;
- 6) balance, oven, and accessories required for determining the moisture in the samples.

How many stations are necessary? Where environmental conditions are uniform, as in Russia, where similar topographical and climatic conditions prevail over long stretches, the number of stations may be relatively limited. On the contrary, in Italy (as in Greece), with the exception of the valley of the Po, which is fairly uniform, the country varies greatly, even within limited zones, so that it would be necessary to have so many stations that the project becomes almost impossible.

Nevertheless, however variable the geographical distribution of meteorological phenomena harmful to crops may be, the nature and signification of the problems of agricultural meteorology remain the same. Thus, in northern Italy, the district in which wheat suffers from lodging includes all the Po valley, but in central and southern Italy, and in the mountain districts, the action of rain with wind is usually discontinuous, oftendisappearing entirely, without any regularity, in localities sheltered from the wind, according to the topography of the land. The problem, however, is the same in each case: — to create a wheat which is both resistant to lodging and a good producer. If it be assumed that wheat suffers from lodging in 200 stations, if in one of these a wheat with a resistant culm were produced, this type could be introduced with a great

probability of success in all the other 199 stations, wherever they may be situated.

Agricultural research which aimed only at solving well-defined problems connected with analyses of agricultural meteorology could, therefore, be carried out in a relatively small number of stations if it were known at what points and to what extent a certain phenomenon is harmful to a given crop. The agricultural stations, and agricultural schools and institutes forming a network in all the civilised countries of the world could, if adequately fitted up, be used as agricultural meteorology stations. To this list might be added the thermo-hyetometric stations, convents, agents and directors of farms, etc. situated even in most distant lands, who could take observations and help to solve the important problems of agricultural geography and meteorology. Each first class station of agricultural meteorology (agricultural stations and schools), together with the second class stations (thermo-hyetometric) and points of observation (parishes, etc.) dependant on it, form a *fundamental principle of the system (network)*.

TABLES OF GROWTH (*their meaning, construction and use in determining a critical period*). — The data obtained in the stations are collected and classified in tables of growth. Plants are modified during the passage from germination to ripening of the fruit, but the modifications which occur are neither gradual nor continuous. There are relatively short phases during which the plant is greatly modified (disappearance of certain organs and formation of new ones); it then remains anatomically and physiologically stationary for a long period, till another phase takes place. There are, thus, *phases of growth* (flowering, earing, etc.) and *interphasal periods* or *subperiods* between two successive phases. It may be assumed that the structure and requirements of a plant remain constant throughout a sub-period.

This phenomenon may be represented by a discontinuous curve, composed, however, of elements almost parallel to the line of the  $x$  joined by almost parallel segments to the line  $y$ .

The growing period of cereals is divided into sub-periods as follows: —

- 1) from sowing till the seedling appears;
- 2) from this phase till winter interrupts growth;
- 3) from this interruption till growth restarts in spring;
- 4) from the restarting of growth to earing;
- 5) from earing to complete maturity.

For each of these sub-periods there is a special table — table of growth — in which are noted all the meteorological and phenological factors of the plant studied, as, for example: —

Table IV. — Wheat.	Station.....	Year.....
Fourth sub-period — From restarting of growth to earing.		
1) Variety.		
2) Date when growth restarted in the whole field.		
3) Remarks on tillering during the 4th. sub-period		

By tillering is meant the emission of lateral shoots, which usually takes place in autumn, but which may occur in a cold, late spring, as is frequently found in the mountains.

- 4) Lengthening of internodes. . . . .
  - a) day when first observed in a few plants . . . . .
  - b) day when observed for the majority of the plants . . . . .
- 5) Degree to which temperature, humidity, sun, etc., favour or inhibit the growth of the internodes. — . . . . .
- 6) Date of appearance of first ears . . . . .
- 7) Date of earing of the majority of plants . . . . .
- 8) Development of this phase, whether uniform, rapid or slow . . . . .
- 9) Influence of weather on earing. . . . .
- 10) Duration of 4th. sub-period . . . . .
- 11) Note, during the 4th. period:
  - 1) frosts . . . . .
  - 2) storms . . . . .
  - 3) drought. . . . .
  - 4) clouds . . . . .
  - 5) other meteorological phenomena . . . . .
- Note, in each case:
  - a) date and duration. . . . .
  - b) intensity. . . . .
  - c) damage caused to plants . . . . .
  - d) effect on soil (washing, baking, cracking, etc.) . . . . .
- 12) Degree to which the variety grown proved resistant to adverse meteorological factors (drought, lodging, excessive moisture, etc.) . . . . .
- 13) Injury by disease or insect attacks . . . . .
- 14) Degree to which atmospheric variations favoured the appearance of disease or insects . . . . .
- 15) Cultivation of plot during the 4th, sub-period . . . . .

TABLE I. — *Moisture of soil, height of plants and depth of roots.*

Month and day	Moisture of soil (%)			Date of last rain before taking of sample	Depth of roots, inches	Height of plant, inches
	Active layer	Virgin layer	Subsoil			

*Soil moisture.* — The periodical determination of the soil moisture at different depths is of great interest, increasing with the frequency with which the determinations are made. However, in view of the amount of work required it is best to allow the directors of the various first class agricultural meteorology stations to decide for themselves the frequency with which such determinations shall be made.

Besides the periodical determinations the soil moisture must be taken at two moments — 15 days before earing, and at the beginning of this phase.

*Height of plants.* — The height of the plants before earing is measured from the level of the ground to the base of the highest leaf, and after earing from the level of the ground to the tip of the ear. The day the one method, is replaced by the other account must be taken of the two factors bearing on the height of the plant calculated from the ground level to the base of

the highest leaf on one hand, to the tip of the ear on the other, as, for example,  $\frac{72 \text{ (stem)}}{76 \text{ (ear)}}$

The average height of 10 normal plants taken haphazard here and there represents the average height of all the plants.

*Depth of roots.* — A lump of soil, together with all the plants on it, is raised about 6 inches, and the depth measured on the vertical section. This determination is made 3 times: — 1) when growth restarts; 2) 15 days before earing; 3) at the moment of earing.

TABLE II. — *Number of plants and culms; vigour of tillering; average weight of dry mass of plants; number and weight of weeds.*

Month  and 'day	Grasses studied								Weeds		
	Number of plants with						Total number of culms	Weight in grams of dry seedling	Vigour of tillering	Number of samples	Weight in grams in dry condition
	one culm	two culms	three culms	four culms	many culms	Total number of plants					

N. B. — This table must be filled in at the moment when the internodes begin to lengthen.

1) *Vigour of tillering.* — This is calculated by dividing the total number of culms by the number of plants.

2) *Determination of the weight of the plants and weeds.* — In four different parts of the plot the plants are uprooted from about  $\frac{1}{4}$  sq. yard; the weeds are separated from the plant studied; the root system is removed and the green part left to dry; when a constant weight is obtained the value is entered in the table.

TABLE III. — *Number of plants and culms; vigour of tillering; vigour of earing; weight of dried mass of the plants; number and weight of weeds.*

Month  and day	Grasses studied									Weeds		
	Number of plants with					Number of culms			Weight in grams of dried plants	Vigour of tillering	Number of plants	Weight in grams in dry condition
	one culm	two culms	three culms	four culms	many culms	Total number of plants	plants earing	plants not earing				

N. B. — This table must be filled in at the end of the earing stage.

TABLE IV.

Month	Meteorological observatory													
	Air temperature							With wet-bulb thermometer			Percentage of relative humidity			
	7h.	13h.	21h.	Total	Average	Maximum	Minimum	7h.	13h.	24h.	7h.	13h.	21h.	Average

TABLE V. — *Temperature of soil.*

Date	At the surface				In active layer				In virgin layer				In sub-soil			
	7h.	13h.	21h.	Average	7h.	13h.	21h.	Average	7h.	13h.	21h.	Average	7h.	13h.	21h.	Average

TABLE VI.

Date	Rain		Mist				Clouds	Storms	Other meteorological phenomena
	in inches (or mm.)	duration	7h.	13h.	21h.	Average			

The table of growth (composed of the above tables) is reproduced because it contains all the material necessary to a complete study of agricultural meteorology. For each variety there will be a table of growth corresponding to each of the interphasal periods.

**DETERMINATION OF THE CRITICAL PERIOD.** — The yield in fruit is the measure by which the more or less favourable action of meteorological phenomena must be judged. The higher the yield the more favourable was the weather during the growing period in general and the critical periods in particular. If the data concerning wheat at station A from 1901 to 1910 were available the following facts could be deduced: — there is no relation between total precipitation and yield in grain or between yield and total precipitation during the 1st., 2nd. and 3rd. sub-periods. If, however, the data on the yield and total rainfall during the 4th. sub-period are compared, a direct relationship is seen to exist. The critical rain period of wheat is, then, the 4th sub-period.

By limiting in this way the field of research to a relatively narrow scope it is easy to define exactly a critical period. No important phenological action is observed between the restarting of growth and the earing phase. The critical period, then, is the earing phase. At this moment the plant does the greatest amount of work by elaborating the enormous quantity of plastic substances necessary for the formation and development of the caryopses and by consuming a great amount of water. There is an average of about 40 days between the earing and ripening phases. During this time occurs the whole process of growth, the last phases succeeding each other rapidly — flowering, development and ripening of the caryopses.

To assure a good wheat harvest abundant rain is necessary during the decade, or two decades, preceding earing so that the plant may have the moisture necessary for rapid and strong growth. In warm countries, where there is a great probability of drought during the earing period, the critical period just mentioned is very evident and has a marked influence on the harvest. In proportion as the cold northern countries where rain is nearly always plentiful at the requisite time are approached, all relation between precipitation and yield disappears, while other critical periods arise, as, for example, an inverse relation between yield and rain during flowering.

The specific action of all the other meteorological factors could be established in a similar way.

THE MANNER IN WHICH KNOWLEDGE OF THE CRITICAL PERIOD, PHENOLOGICAL MAPS AND WEATHER CHARTS PERMITS AN INCREASE OF YIELD BY ADAPTING THE VARIOUS CEREALS TO THE CLIMATE. — When a scale of the yields has been established (*i. g.* for wheat, cwt of grain per acre), it is possible to distinguish the zones of good, medium and bad harvests. Thus, the zone of good harvests includes districts where the average yield of wheat exceeds 13 cwt. per acre, that of poor harvests where the yield is less than  $9\frac{1}{2}$  cwt. per acre; the medium zones includes the districts with yields between  $9\frac{1}{2}$  and 13 cwt.

The aim of agricultural meteorology is to increase the zone of good harvests at the expense of the other two. Statistics are but a statement of facts; the expression "bad harvest" merely means that the meteorological factors during the period of growth in general and the critical periods in particular are unfavourable to the growth of the plant, but does not show which was the unfavourable factor or the means to remedy it. To do this agricultural meteorological analysis is necessary. Many meteorological phenomena may damage wheat, for example, in Italy. In the south there may be: —

1) warm, dry winds (sirocco, "favonio") which, during the ripening of the ear (5th. sub-period) cause scorching, followed by hastened ripening, drying up of the grain, and, while the plants are still strong, the caryopses lose food material or do not form at all. This is particularly serious in light soils or where there is only a small layer capable of being cultivated and, in some years, within a few days, the yield is reduced by 25, 30, or even 50 %.

2) lack of rain during the 10 or 20 days preceding earing;

3) prolonged drought during the period following sowing.

Rust is little to be feared because excessive humidity in spring occurs rarely and only over very limited areas. Lodging is unknown because in the islands, most of Calabria and in Basilicata hard and semi-hard grain with short, strong straw is grown.

In central and northern Italy, on the contrary, the following facts must be noted with regard to climate: —

1) in the valley of the Po, particularly in the lowest part, wheat almost invariably suffers from excessive moisture which causes rust with a resultant serious decrease of yield;

2) lodging caused by wind and heavy rain at the time of the formation and development of the caryopses may lower the yield by 20 to 25 %;

3) considerable damage by late spring frosts.

Such is the knowledge, relatively general, at the present day, when the network of agricultural meteorological stations is to begin its work, aiming at *a*) the determination of the critical period of wheat with respect to the meteorological factors as discussed above, *b*) the preparation of phenological maps, and *c*) weather charts.

Once the critical period is known the comparison of the phenological maps and weather charts allows the suitability of a plant to local climatic conditions to be easily determined. If, for example, at A, wheat ears on May 10 on an average, and if, during the last decade of April and the first decade of May, the probability of drought is 75 and 90 % respectively, this will show why the average yields in this district are relatively low. Once the reason of the poorness of the yield is established it may be remedied in three ways:

1) Change the time of the critical period phase and make it coincide with a more favourable meteorological moment.

*E. g.* the *f* variety of wheat at the station A ears on an average (see phenological map of earing of wheat) on May 12, and the probability of drought during the third decade of April and the first decade of May is 90 and 95 % respectively (see weather charts for drought for the 3rd. decade of April and the 1st. decade of May). This accounts for a low yield. In the first and second decade of April, on the contrary, the probability of drought at A drops to 10 and 15 % respectively. By earlier sowing or by using an earlier type of *f'* wheat, so that earing takes place between April 20 and 25, this drawback could be remedied in part at least.

2) Artificial modification, during the critical period, of meteorological factors, *e. g.* control of frost by smoke, of drought by irrigation, etc. Brilliant results have been obtained with fruit in California by forecasting cold by 24 to 48 hours, thus allowing growers to decrease or even nullify injurious effects by burning heavy oils or other substances which surround the tree with thick, protective smoke.

3) The introduction or production of types of increasing resistance to drought, frost, rust, lodging, etc.

Modern experimental research in biology in various countries has clearly shown that, by hybridisation and subsequent selection, it is possible to unite in one variety the good characters existing in

two distinct varieties and to eliminate undesirable characters. In each particular case the breeder must aim at uniting high yield with resistance to the harmful meteorological character most frequent in the district. Thus, at Svalöf (Sweden), M. NILSSON has obtained types of wheat resistant to cold, and at the same time, excellent yielders by crossing the most productive varieties slightly resistant to cold (English Square-head) with native Swedish wheat very resistant to low temperatures.

This acclimatation of non-native types and creation of new types by crossing and selection would be the most important work of agricultural meteorological stations of the 1st. class. In the choice of these, therefore, use would be made of agronomic and agricultural Institutes already existing and not of the meteorological Institutes which may cooperate with them but cannot form centres for new research.

The following example shows that agricultural meteorological study is not only necessary where soil is cultivated for the first time, but that it may give excellent results in districts where intensive culture has been carried out for a long time by determining a better adaptation of crops to the climate of different districts. In the province of Bologna (northern Italy) each farm may be said to grow three varieties of wheat — Rieti, Gentil rosso and Hybride inversable de Vilmorin, distinguished by the following characters :

1) RIETI : resistant to rust but lodges easily ; in favourable years, *i. e.* when it does not lodge as a result of storms, it yields about 17  $\frac{1}{2}$  cwt. per acre ;

2) GENTIL ROSSO : very subject to rust and lodging ; in favourable years, without excessive humidity and destructive storms, it may yield over 19 cwt. per acre ;

3) HYBRIDE INVERSABLE DE VILMORIN : subject to rust but resistant to lodging ; when the humidity is not excessive it may yield 16  $\frac{3}{4}$  cwt. per acre.

Gentil rosso and Hybride inversable are of recent introduction, and other varieties, now under observation in various agricultural institutes, will finally be added to the pre-existing varieties, causing a mixture of wheat which is not always desirable. A single variety best suited to the climate had not been adopted because, it is argued, there is no such variety and none which suffers from the same two causes at the same time, therefore, if in any year one variety fails, there is always one which succeeds, thus compensating for the loss. This is false reasoning. Gentil rosso, when it does not lodge, produces up to 19 cwt. per acre, Hybride inversable only 16  $\frac{3}{4}$ , *i. e.* 2  $\frac{1}{4}$  less ; but the first lodges easily, whereas the second does not. Lodging causes a loss of nearly 4 cwt. per acre, thus reducing the yield from 19 to 15 cwt. The probability of heavy rainfall and wind during the 5th. sub-period in the province of Bologna is, moreover, 80 %. In a period of 5 years there would be : — GENTIL ROSSO  $19 + (15 \times 4) = 79$  cwt ; HYBRIDE INVERSABLE DE VILMORIN  $16 \frac{3}{4} \times 5 = 83 \frac{3}{4}$ . Thus, in the province of Bologna, where the probability of lodging is 80 %, the Vilmorin hybrid is preferable to Gentil rosso.

When, on the contrary, the probability of storms in the 5th. sub-period falls to 20%, GENTIL ROSSO should be preferred: — HYBRIDE DE VIL-MORIN  $16 \frac{3}{4} \times 5 = 83 \frac{3}{4}$ ; GENTIL ROSSO  $(19 \times 4) + 15 = 89$  cwt.

*Agricultural meteorology is, therefore, indispensable if an exact idea of the real productivity of a species in a given district is to be determined.*

The mere fact that a given variety of wheat is grown by preference in a given district is no proof that it is the best, suited to this district. New types are often on the market which may completely supersede the native types, to be superseded later in their turn by other new types. In all such cases it is the character "productivity" which guides the farmer in his choice of seed; but productivity is influenced to a marked degree by climatic conditions, and consequently, varies from one district to another, so that the adoption of new types should be preceded by a careful study of agricultural meteorology.

Agricultural meteorology thus gives a twofold result: —

1) it allows a better distribution of the different varieties of a cultivated species; *i. e.* it shows the districts best suited to each variety from the point of view of local climatic conditions;

2) it guides the selector in his research aiming at uniting to the best advantage in a single type, productivity and resistance to the most destructive meteorological phenomena of the different districts.

The work of adapting crops to climate is difficult, but it cannot fail to lead, in part at least, to positive results, and considering the size and complexity of the problem, these results, even though they be but small, represent large figures.

Unfavourable conditions in Italy diminish the grain harvest, on an average, by over 3 cwt. per acre, and though only  $\frac{1}{2}$  cwt. per acre were gained, the profit would be 9 432 980 cwt. representing a considerable value.

What has been said for wheat applies equally to all other cultivated plants; what has been said for Italy applies to all the countries of the world. On the other hand, it is seen that the network of agricultural meteorology stations is already outlined by the many agricultural schools and institutes and the thermo-hyetic stations possessing the premises, instruments, experiment fields and technical staff. All that is required is to collect, co-ordinate and develop all this latent or dispersed activity, so that the cost of the formation and upkeep of the new service shall be limited.

257 — **The Relation of Winter Temperature to the Distribution of Winter and Spring Grain in the United States: Why Cereals Winterkill.** — SALMON, S. C., I. *Journal of the American Society of Agronomy*, Vol. IX, No. 8, pp. 353-380; II. *Ibid.*, Vol. IX, No. 1, pp. 21-24. Washington, 1917.

I. — In northern districts winter cereals usually give a higher yield than spring cereals, but they are much less widely distributed because they are naturally excluded from zones where the climate is too severe to allow the young plants to survive the winter. The injurious action of the winter may have four effects: —

1) HEAVING. — This is due to expansion and contraction of the soil by alternate freezing and thawing; the roots are broken and exposed to

the air. Shallow sown plants suffer least, as the whole plant will then be lifted without breakage of the underground parts. Heaving is most common in the eastern States, especially in wet, badly drained plains.

2) **SMOTHERING.** — Alternate freezing and thawing sometimes turn the snow into an ice sheet through which the air cannot pass, thus suffocating the plants by lack of air and accumulation of carbonic acid.

3) **PHYSIOLOGICAL DROUGHT.** — This occurs when the soil is frozen and the plant can no longer obtain moisture from it. All the anatomical characters which tend to limit transpiration should, therefore, be in correlation with resistance to cold. Turkey and Kharkov wheat, winter rye and winter Turf oats, known for their resistance to cold have marked xerophytic structures — narrow leaves and prostrate habit of growth, which partially protect the plant from the action of wind (KOLKUNOW, SINZ, etc.). The author and his collaborators, in a study on several varieties of winter wheat, rye, barley and oats, found no definite relation between resistance to cold, cell structure, epidermal covering and ability to control transpiration. Recent studies have, however, shown that a reduction of the leaf area in relation to the length of the root as expressed by the ratio of root length to leaf area does influence the resistance of young plants to cold. In Turkey wheat this ratio is 25 % greater than in Fultz wheat, a less hardy variety, and 40 % greater than in common oats and barley. Physiological drought may be considered, if not as the only cause of winterkilling, at least as the most important.

4) **DIRECT EFFECT OF LOW TEMPERATURE.** — This acts in many ways: —

a) *Mechanical action.* — Injury to the tissues caused by the formation of ice.

b) *Desiccation of the protoplasm.* — Low temperatures cause withdrawal of water to the intercellular spaces, where it freezes; when later, the ice thaws rapidly the moisture can no longer be absorbed. At  $-13^{\circ}\text{C}$ . the loss of water is 63.7 %; at  $-15.2^{\circ}\text{C}$ ., 79.2 %.

c) *Coagulation of the proteids.* — In plants resistant to cold this only takes place at very low temperatures; thus for pine needles a temperature of  $-40^{\circ}\text{C}$  is required, in winter rye  $-15^{\circ}$  and in begonia, which is very sensitive to cold,  $-3^{\circ}\text{C}$ . This coagulation is accompanied by denaturing of the proteids, caused, perhaps, by increased acidity of the sap, so that they can no longer be reabsorbed. This theory is held by GORKE but contradicted by CHANDLER's experiments, which showed zinc sulphate, one of the salts which readily coagulate proteids, to increase rather than to diminish resistance to cold.

LIDFORSS, in his studies on *Holosteum*, *Cerastium*, *Lamium*, *Veronica*, *Senecio*, *Viola*, *Fumaria*, etc., observed that, on the approach of winter, the starch in the tissues of these plants changed to sugar, which, by changing the concentration of the sap, reduces the freezing point. These phenomena of the protective action of various substances due to the lowering of the freezing point have formed the subject of much research (MAXIMOV, etc.), which confirms the theory of LIDFORSS.

II. — The specific action of low winter temperatures on winter ce-

reals is clearly shown by a study comparing the northern boundary of different varieties with the isotherms of the minimum temperatures during January and February.

**WINTER WHEAT.** — Its northern limit corresponds approximately to the isotherm of  $10^{\circ}\text{F}$  ( $-12.2^{\circ}\text{C}$ ). Cold resistant varieties may exceed this limit if the seed is well protected by a covering of snow.

**WINTER BARLEY.** — Its northern limit coincides with the isotherm of  $20^{\circ}\text{F}$ . ( $-6.6^{\circ}\text{C}$ ). It is successfully grown to the west of the Rocky Mountains and to the south of the Ohio and Platte rivers.

**WINTER OATS.** — Its northern limit corresponds to the isotherm of  $30^{\circ}\text{F}$  ( $-1.1^{\circ}\text{C}$ ). They may be grown, in the north, as far as Central Tennessee and Arkansas and southern Maryland and Oklahoma.

SOIL PHYSICS,  
CHEMISTRY  
AND  
MICROBIOLOGY

258 — **Effect of Decomposing Organic Matter on the Solubility of certain Inorganic Constituents of the Soil.** — JENSEN, C. A. (Assistant in Plant Malnutrition, Office of Biophysical Investigations, Bureau of Plant Industry, U. S. Department of Agriculture), in the *Journal of Agricultural Research*, Vol. IX, No. 8, pp. 253-268. Washington, May 21, 1917.

The experiments described were undertaken to determine if the beneficial action of decomposing organic substances (humus) is due to the solution of the inorganic substances of the soil, and, if so, to what extent. Water extracts of green barley hay, sweet clover and alfalfa were prepared by saturating 70 gm. of each of these substances in a flask with distilled water, and allowing them to ferment for 14 days. After this period the substances were thoroughly shaken with 1500 cc. of distilled water, and filtered, first through muslin, then through a Chamberland filter. The insoluble residue was again treated in the same manner and other extracts obtained from it. The extracts thus obtained were added to soils in the proportion of 500 cc. of solvent to 250 gm. of soil. The soils used were clay loam and sandy loam,

It was found, in the first place, that by extracting soils with these solutions, two to five times as much calcium was removed as was added in the extracts. In most cases even more magnesium was removed than was added, the increase varying from a small fraction to 80 %. Iron and phosphoric acid were removed in smaller quantities than they were added in the extracts, but the iron dissolved exceeded that dissolved by water by 1.7 to 5.4 times. The solvent action of the different extracts was about the same whether they were prepared from leguminous or non-leguminous plants.

Extracts obtained in a similar way from cow manure removed less calcium from the soil than did vegetable extracts, but their action was the same for the other mineral constituents.

Both the organic and inorganic salts of the aqueous extracts seem to contribute to the solution of the mineral substances of the soil.

Artificial green manures (barley hay, sweet clover, bean straw, alfalfa, etc.) kept moist till thoroughly decomposed, and gave extracts which removed a greater quantity of calcium than was added; they also removed amounts of magnesium, phosphoric acid and iron in excess of those dissolved by water alone. The green manure extracts gave no alkaline

reaction to phenolphthalein and no acid reaction to methyl orange. When the soil was mixed with 3 % green manure and stable manure and left till partially decomposed, the solubility of the calcium and phosphoric acid increased from 30 to 100 %.

To study the action of the organic constituents of the extracts tested, green manure and sugar were hydrolysed with strong acid, washed till free from acid, then extracted with ammonia. When the ammonia was eliminated these extracts represented artificial humus solutions free from calcium, magnesium, iron and phosphoric acid. These extracts, when added to soil, increased the solubility of the calcium as compared with its solubility in water by amounts varying from a few parts to 240 parts per million of soil. They also increased to a lesser extent the solubility of magnesium, phosphoric acid and iron.

In short, in the soils tested, the solubility of calcium, magnesium, iron and phosphoric acid is appreciably increased by the addition of green manure, stable manure or their extracts. This increase in solubility is due, partly to the action of the inorganic salts contained in these substances, and partly to the solvent action of the organic compounds formed during decomposition. The fact that a deficiency in soluble iron causes certain types of chlorosis suggests that the beneficial effect of the addition of organic matter to citrus soils depends partly on its solvent action on iron and other soil compounds, though this has not yet been definitely proved.

259 - **The Proof of Microbial Agency in the Chemical Transformations of Soil.** — CONN, H. J. (New York Agricultural Experiment Station), in *Science*, Vol. XLVI, No. 1185, pp. 252-255. Lancaster, Pa., September 14, 1917.

Care must be taken to avoid inexact statements and ill-founded conclusions as to the part microorganisms play in the chemical changes occurring in soil. In soil microbiology there are statements and deductions similar to those found regarding pathology till light was thrown on it by the fundamental postulates laid down by KOCH for the study of pathogenic bacteria.

Extending these postulates, by analogy, to bacterial activity in soil, the author lays down the following principles for research in soil microbiology :

- a) The organism to which action is attributed must be shown to be present in the soil in an active form when the chemical change studied is taking place ;
- b) this organism must be present in larger number, under such conditions, than in the same soil in which the chemical change is not occurring ;
- c) it must be isolated and studied in pure culture ;
- d) the same chemical change must be produced by the organism in experimentally inoculated soil, the test being made, if possible, in unsterilised soil.

These facts can be shown by the cultural methods used up to the present. It must, however, be remembered that they may lead to errors because naturally inactive organisms may be present which become active under cultural conditions, or the opposite may occur. Cultural methods must, therefore, be checked by others; the microscope may be useful in this respect, but it may prove necessary to devise entirely new methods.

## 260 - The Decomposition of Soil Protein Substances Through the Action of Bacteria.

— ROBINSON, R. H. and TARTAR, H. V., in *The Journal of Biological Chemistry*, Vol. XXX, No. 1, pp. 135-144. Baltimore, May, 1917.

The experiments described were carried out at the Chemical Laboratory of the Oregon Agricultural Experiment Station, Corvallis. The function of bacteria in the production of ammonia from the protein substances in soil has long been known. How these proteins are acted upon, whether it be a hydrolytic process brought about by enzymatic action, whether it be an oxidative one, or a more complex chemical reaction is still unsolved. This led the author to undertake a series of experiments to ascertain, by controlling the influencing factors as much as possible: — 1) the chemical changes proteins undergo when acted upon by bacteria; 2) the cause of partial ammonification of protein substances; 3) the nature of the reactions in general.

The proteins used were blood fibrin, egg albumin and peptone; the bacteria: *Bacillus subtilis*, *B. mycoides* and *B. vulgaris*. The results obtained show that: —

1) All the nitrogen forms are more or less changed by the action of the bacteria and the end-product ammonia is formed. In no case was one form of nitrogen completely destroyed.

2) The rapidity of action varies greatly with different protein substances; casein showed no further change after a few days, whereas gliadin continued to ammonify after 30 days.

3) One organism does not act alike upon different proteins. The relative proteolytic activities of the organisms used depend on the proteins acted upon.

4) The monoamino-acid nitrogen and diamino-acid nitrogen of the protein are the chief sources of the ammonia formed by bacterial action.

5) The similarity of chemical change between the action of acid hydrolysis and that of bacteria indicates that the latter is largely hydrolysis to the point of formation of various amino-acids.

6) No toxic substance that would inhibit complete ammonification of a protein is formed.

PERMANENT  
IMPROVEMENTS:  
DRAINAGE AND  
IRRIGATION

261 - Irrigation of Orchards in U. S. A. — FORTIER, SAMUEL, in *U. S. Department of Agriculture, Farmers' Bulletin* No. 582, pp. 40, 30 figs., illustrations. Washington, D. C., October, 1917.

This bulletin is a revised edition of that on the irrigation of orchards in the west of the United States, published in 1910.

In the arid and semi-arid districts of the United States the irrigation methods vary with the water supply, climate, soil and situation of the land. The cost of installing and maintaining a system varied greatly. The value of water for irrigation has greatly increased of recent years, and in many districts there is a scarcity of water at certain times. For these reasons many orchard-owners have installed pumps to raise underground water. In 1914 there were in California alone 24 600 plants for raising water for orchard irrigation purposes. In other parts of the West reservoirs are being built

to supplement the insufficient flow in late summer. The canals, previously simply open ditches in earth, have been improved and lined with concrete, and, in many cases, replaced by underground pipes to prevent loss of water. The water is often supplied by companies, who have also greatly improved the distribution of their water.

The trees are planted in lines, squares or hexagons. The most common method of irrigation is by furrows between the rows of fruit-trees. These furrows vary in depth, length and distance apart according to the soil, surface, quantity of water to be used, etc. The head ditches and those for distributing the water in the furrows may be built in various ways, some of them very expensive and only justifiable for large orchards. The bulletin describes the most common types of head flumes, which may be of wood, cement or concrete. The number of furrows between the rows of trees varies with the space between the rows, the age of the trees, the depth of the furrow and the character of the soil. Deep ditches are usually preferred, the most common depth being 8 inches. The grade of the furrows varies; in ordinary soils it does not exceed 3 to 4 inches per 100 feet. The machine generally used for tracing furrows in citrus orchards consists of a sulky frame to which are attached two or three double moldboard ploughs; a 12 to 14 inch corn lister is also used for deeper furrows. The length of the ditches varies from 300 to 600 feet. The time required to irrigate depends on the quantity of water used, the length of the furrow and the nature of the soil.

The orchards are also sometimes irrigated by the basin method by forming, midway between the rows of trees, ridges at right angles to each other. By this method the land is divided into squares with a tree in the centre of each; more rarely each square contains four or more trees. This method has recently been renewed in California because, while thoroughly moistening the soil, it allows the growing of alfalfa and other leguminous plants, to the great advantage of the orchard.

Many orchard owners base the interval between two irrigations on an examination of the vegetation; they renew the stream when the trees show visible signs of suffering, *i. e.* when their leaves begin to change colour or curl. This method is not practical and it is the moisture content of the soil which should be considered. In the state of Washington there are three or four waterings at intervals of 20 to 30 days, the first being given in April or early in May. In Idaho there are three irrigations, beginning about June 15. In Montana the orchards are irrigated towards July 15, August 10 and August 20. In southern California the citrus trees are watered six or seven times during the summer at regular intervals.

The bulletin also deals with loss by evaporation and percolation and with drainage which, under certain conditions is frequently necessary.

MANURES  
AND MANURING

- 263 - **The Influence of Fineness of Division of Pulverised Limestone on Crop Yield as well as the Chemical and Bacteriological Factors in Soil Fertility.**—KOPELOFF, N., in *Soil Science*, Vol. IV, No. 1, pp. 19-67 + 2 figs., bibliography of 124 publications. Baltimore, July, 1917.

After discussing in detail the work published on the liming of soils the author gives the results of his experiments made on various soils with pulverised limestone passed through sieves of 20-40, 60-80, 100-200 and more than 200 mesh. These experiments were compared with control plots with burnt lime.

An increase in the fineness of the lime gave a proportionate increase in the yield and nitrogen content of crimson clover. The finer the lime the more rapid was the neutralisation of the acidity of the soil and the greater the bacterial processes of ammonification, nitrification and nitrogen fixation. In the case of barley, buckwheat and rape, fine limestone without nitrogen gave yields equal to those obtained with coarse limestone with an application of 660 lbs. of ammonium sulphate per acre. Limestone passed through a 200 mesh sieve may be considered as efficacious as burnt lime. An increase in the fineness of the limestone decreases the lime-requirement of the soil, but the drainage waters show a smaller loss of ammonia and nitric nitrogen, but an increased loss of calcium.

- 264 - **Fermentation of Manure Treated with Sulphur and Sulphates: Changes in Nitrogen and Phosphorus Content.**—AMES, J. W. and RICHMOND, T. E. (Ohio Agricultural Experiment Station), in *Soil Science*, Vol. IV, No. 1, pp. 79-89, bibliography of 21 publications. Baltimore, July, 1917.

It is known that the addition of acid phosphate to manure helps to preserve the nitrogen, and the treatment of manure with gypsum is also a common practice. Recently, however, LIPMAN and his co-workers have called attention to the beneficial effect of treating compost heaps with sulphur and the by-products of mineral phosphates ("floats") which supply available phosphorus (1). To study the influence of sulphur and other materials on the fertilising value of manure as measured by its composition and effects on crops, the authors carried out experiments with solid horse manure and cow's urine treated and untreated with sulphur, calcium sulphate and acid phosphate. The manure was left to ferment in large containers and applied to small plots. The nitrogen, phosphorus, sulphur and dry matter in the manure were then determined.

After 250 days' fermentation the loss of dry matter in horse manure mixed with a litter of fine cut straw was:—32.5 % when untreated, 21.8 % when treated with 342 grams of acid phosphate or 407 grams of calcium sulphate per 30 lbs. manure, and 18.2 % when treated with 90 grams of flowers of sulphur per 30 lbs. of manure. Manure treated with acid sulphate, calcium sulphate and sulphur only lost about 3.5 % of its total

(1) LIPMAN, J. G., McLEAN, H. C. and LINT, H. C., The Oxidation of Sulphur in Soils as a Means of Increasing the Availability of Mineral Phosphates. *Soil Science*, Vol. I, No. 6, pp. 533-539, 1916. ID. Sulphur Oxidation in Soils and its Effect on the Availability of Mineral Phosphates. *Ibid*, Vol. II, No. 6, pp. 499-538. (Ed.)

nitrogen, whereas the loss in untreated manure was 10.5 %. Both the water-soluble and the citrate-insoluble phosphorus was decreased in every case. During fermentation manure treated with sulphur increased in acidity, whereas the untreated sample became alkaline.

Sulphur, calcium sulphate and acid phosphate were all very effective in preventing loss of nitrogen from urine. In 5 weeks the untreated urine lost 80 % of its nitrogen, that treated with 7 grams of sulphur per 500 cc. lost 10 %, that treated with 27 grams of calcium sulphate per 500 cc. lost 9.72 % and that treated with 27 grams of acid phosphate per 500 cc. lost 5.1 %. Sulphur also prevented the formation of ammonium salts, whereas with calcium sulphate 68 % of the total nitrogen was transformed into ammonium sulphate. In urine treated with acid phosphate and kept in an open jar for 27 days no ammoniacal nitrogen was formed, but after being kept 3 months in a closed jar it turned alkaline and evolved ammonia.

**265 - Garbage Tankage, its Composition ; The Availability of its Nitrogen and its Use as a Fertiliser.** — SCHROEDER, P. J. (Bureau of Soils, U. S. Department of Agriculture), in *The Journal of Industrial and Engineering Chemistry*, Vol. IX, No. 5, pp. 513-518. Easton, Pa., May, 1917.

In about half of the towns of the United States garbage is treated by 29 companies and municipalities for the extraction of fat ; the residue, called " tankage " is considered as a low grade fertiliser. In 1914, 1 200 000 tons of garbage were dealt with yielding, besides the fat, 173 000 tons or 15 % of tankage, valued at \$ 1 157 000 at pre-war prices, but now worth almost twice as much. If the garbage of all towns with a population of more than 30 000 were so dealt with, the production of degreased garbage would exceed 345 000 tons and be worth over 4 million dollars.

In some cases the bits of glass, tin, etc. are first eliminated from the garbage ; it is then treated by one of the following methods : —

- 1) Cooking under pressure with steam (tanking) ; elimination, as complete as possible by pressing, of water and fats liberated, from which the oil is separated by settling and skimming ; extraction with gasoline of the grease remaining in the solid residue after it has been dried.

- 2) Crushing to render the particles uniform in size ; drying, followed by extraction with gasoline ; grinding of the solids for tankage.

- 3) Heating with boiling gasoline to evaporate the water and extract the fat.

In some plants where the first process is used the dried tankage is not extracted with gasoline for the recovery of the fat ; in others the aqueous solution is evaporated to a sticky consistency and mixed with the degreased tankage which is then re-dried.

In appearance garbage tankage is a coarse, brown powder, either granular or finely fibrous ; it generally contains bits of bone, crockery or glass in proportions varying with the degree of care with which the sorting has been carried out. The appended table gives the average chemical composition of 75 samples of raw garbage and 20 samples of tankage from various plants ; the fat was not extracted from four of these last samples.

*Average composition of treated and untreated garbage.*

	Moisture	Ash	Ether extract	Potash	Nitrogen	Phosphoric acid	Combustible matter
Raw garbage . .	73.78%	3.60%	5.32%	0.27%	0.70%	0.43%	22.63%
Tankage . .	3.67*	29.15*	4.92 <sup>1</sup>	0.80*	2.78*	3.56*	

\* Percentages calculated on moisture free basis.

Attempts have recently been made to use tankage as cattle food by employing flotation methods to remove the hard matter. It is, however, largely used as fertiliser material, to which, by its composition, it is well suited. It has only been used successfully as a low grade fertiliser and its high organic content makes it of increased value for soils poor in humus.

Tankage is sold at a relatively low price because of the general opinion that its nitrogen is of a limited fertilising value. The author's investigations show this opinion to be erroneous; estimations by the alkaline permanganate method showed 40 % and more of assimilable nitrogen as compared to 57 % in cottonseed meal, and nitrification tests gave equally good results. About  $\frac{1}{4}$  of the total nitrogen of garbage is soluble in water, and this proportion may be increased considerably by treatment with sulphuric acid.

Seeing that other high-grade organic nitrogen fertilisers, such as cottonseed meal and slaughter-house residues, are being used more and more as food for stock, and that garbage tankage contains a large amount of nitrogen, garbage tankage should be more generally used as a fertiliser, thus permitting not only of a more complete utilisation of the garbage, but also of increased municipal profits.

266 - **Effect of Three Annual Applications of Boron on Wheat** (1). — COOK, F. C., and WILSON, J. B. (Bureau of Chemistry, U. S. Department of Agriculture), in the *Journal of Agricultural Research*, Vol. X, No. 12, pp. 591-597, bibliography of 6 publications. Washington, September 17, 1917.

In the experiments described, horse manure, containing sufficient borax to kill fly larvae, was used as fertiliser on plots on which wheat was grown during three successive years to determine whether boron used as a larvicide is detrimental to wheat. At the same time another plot was treated with manure containing colemanite (a borate of lime). There was also one plot used as manured control and another used as unmanured control. The borax was applied at the rate of 154 lbs. of boric acid per acre (a quantity sufficient to kill the larvae) during the first year, and at the rate of 38.5 lbs. per acre during the two subsequent years. The colemanite, a less efficient larvicide, was applied at the rate of 50.75 lbs. of boric acid per acre each year.

In the case of large applications of borax during the first year a considerable yellowing of the young wheat plants was noticed and, as compared with

(1) See R. Aug., 1916, No. 854. (Ed.)

the manured control plot, a reduction of 10 % in the yield during the first two years, whereas the effect of colemanite was hardly noticeable. In the last year all the yields were low except that of the borax-treated plot, which was relatively high.

The wheat absorbed only minute amounts of boron (slightly more, however, from the borax), and the distribution of the boron was relatively uniform in the straw and the grain.

The presence of soluble boron was found in the soil after a heavy application of borax, but not in the other cases. The boron apparently is gradually combined in an insoluble compound and so distributed that the upper 6 inches of soil show little total boron after three yearly additions of borax. There is no evidence of any cumulative action of boron in the soil. It is apparently the soluble boron, not the total boron, in the soil which injures wheat plants.

267 - Occurrence of Manganese in Insect Flower Stems. — MC. DONNELL, C. C. and ROARK, R. C. (Insecticide and Fungicide Laboratory, Miscellaneous Division, Bureau of Chemistry, U. S. Department of Agriculture), in the *Journal of Agricultural Research*, Vol. XI, No. 3, pp. 77-82, bibliography of 16 publications. Washington, October 15, 1917.

AGRICULTURAL  
BOTANY,  
CHEMISTRY  
AND  
PHYSIOLOGY  
OF PLANTS

To detect the adulteration of pyrethrum insect powder (*Chrysanthemum* [Pyrethrum] *cinerariaefolium* Vis.) UNGER (1) recommended testing it for the presence of manganese, which is absent in pyrethrum stems. This statement has been contradicted by other workers. The authors carried out quantitative determinations of the manganese content of the stems and open and closed flowers of pyrethrum of both Dalmatian and Japanese origin.

The analyses showed the manganese content of both stems and flowers to vary considerably, and the difference between the two parts of the plant to be so small that the determination of the manganese content as a control of the amount of stem in an insect powder would be useless. Moreover, pyrethrum from Japan contains more manganese than that from other countries, owing, presumably to the high manganese content of the volcanic soils of Japan. An increase in the manganese content of pyrethrum is accompanied by a slightly higher nitrogen and phosphoric acid content.

268 - The Proteins of the Peanut, *Arachis hypogaea*: The Distribution of the Basic Nitrogen in the Globulins Arachin and Conarachin. — JOHNS, CARL O. and JONES, D. BRESEE, in *The Journal of Biological Chemistry*, Vol. XXX, No. 1, pp. 33-38. Baltimore, May, 1917.

In a recent paper (2) the authors showed that the globulins of the peanut contain a relatively high percentage of basic nitrogen; arachin, the chief protein of the peanut, contains 4.96 %, and conarachin 6.55 %. These values were obtained by the Hausmann method, in which no correction is made for the solubility of the phosphotungstates of the bases, and are, therefore, lower than those obtained by the Van Slyke method, in

(1) UNGER, H., Flores Chrysanthemi, *Pharm. Ztg.* XXXII, 96, 685-686, 1887. — *Id.* *Ibid.*, XXXIII, 23, 166-167; 1888. — (2) See R. Feb, 1917, No. 128. (*Id.*)

which this correction is made. The authors, therefore, analysed these globulins by the Van Slyke method and found both to contain arginine, histidine, lysine and cystine in the following proportions:

*Percentage of Basic Amino-acids in the Globulins of the Peanut.*

	Arachin	Conarachin
Arginine . . . . .	13.51	14.60
Histidine . . . . .	1.88	1.83
Lysine . . . . .	4.98	6.04
Cystine . . . . .	0.85	1.07

The figures for cystine are undoubtedly too low as they represent only the cystine which escaped destruction during the hydrolysis of the proteins with hydrochloric acid.

The two globulins also give a marked reaction to tryptophane. Considering the high proportion of lysine in the proteins of the peanut and peanut meal (which contains about 28 % of protein [ $N \times 6.25$ ] when made from whole nuts, and 45 % when made from shelled nuts), both might be advantageously used to supplement diets deficient in lysine (1). For example, gliadin, the protein of wheat, only contains 1.21 % of lysine; zein, the protein of maize, contains none at all. On the other hand, legumin of the pea and phaseolin of the kidney bean are relatively rich in lysine, containing 4.29 and 4.58 % respectively.

269 - **Sedoheptose, a New Sugar from *Sedum spectabile*.** -- LA FORGE, F. B. and HUDSON, C. S., in *The Journal of Biological Chemistry*, Vol. XXX, No. 1, pp. 61-77. Baltimore, May, 1917.

The aqueous extract of the leaves and stems of *Sedum spectabile* contains a non-fermentable, reducing sugar. Analyses of its crystalline phenyl and bromo-phenyl osazones show it to be a new heptose which the authors call sedoheptose. By reduction of a solution of the sugar with sodium amalgam, two heptahydroxy alcohols, designated as  $\alpha$  and  $\beta$  sedoheptitol were obtained. In all probability sedoheptose is a ketose, as bromine does not oxidise it and the two above-mentioned alcohols probably result from its reduction.

270 - **Influence of Hydrogen-Ion Concentration of Medium on the Reproduction of *Alfalfa Bacteria*.** -- FRED, E. B. and LOOMIS, N. E. (Department of Bacteriology, University of Wisconsin), in the *Journal of Bacteriology*, Vol. II, No. 6, pp. 629-633, 1 diagram, bibliography of 7 publications. Baltimore-London, November, 1917.

MICHAELIS, CLARK and others have shown the hydrogen-ion concentration of the medium to have a great influence on its reaction and the bacte-

(1) OSBORNE and MENDEL (*Journal of Biological Chemistry*, Vol. XVII, p. 325, 1914) and other workers have shown that lysine is essential to the growth of animals. Nutrition experiments (HOPKINS, F. G., *Journal of the Chemical Society*, Vol. CIX, p. 629, 1916) have shown that the animal organism cannot synthesize lysine which must, therefore, be supplied in the food in sufficient quantity to ensure normal growth.

OSBORNE and JONES (*American Journal of Physiology*, Vol. XXIV, p. 438, 1909) found the following different percentages of lysine in the muscle substance of different animals: -- scallop (*Fecten irradiatus*), 5.77 %; halibut (*Hippoglossus vulgaris*), 7.45 %; chicken, 7.21 %; ox 7.59 %. See also B, Jan., 1915, No. 72. (Ed.).

rial processes. Certain species are very sensitive to slight changes, whereas others develop in a medium having considerable variation in reaction. The author studied the effect of this reaction on the growth of *B. radiculicola* from alfalfa.

As culture medium was used a mannitol solution composed of mannitol 10 gm., magnesium sulphate 0.2 gm., monobasic potassium phosphate 0.2 gm., sodium chloride 0.2 gm., calcium sulphate 0.1 gm., distilled water 1000 cc. This solution was divided into 24 parts of 100 cc. each, and the reaction changed by the addition of N/10 sulphuric acid or sodium hydroxide. The hydrogen-ion concentration was determined immediately after inoculation and again two weeks later. The results, given in tables and diagrams, show that the change in hydrogen-ion concentration is much greater with a given increase in acidity than for a corresponding increase in alkalinity, especially after bacterial growth has continued for two weeks. There is a correlation between "hydrogen-ion concentration" and "growth of *B. radiculicola* of alfalfa". This bacterium is much more sensitive to sulphuric acid in mannitol solution than to gram equivalent amounts of sodium hydroxide. The results confirm those of PRUCHA (*New York Agricultural Experiment Station, Cornell, Memoir 5*, pp. 41-47, 1915), who found that normal hydrochloric acid is much more injurious to the multiplication of *B. radiculicola* of alfalfa than equivalent amounts of normal sodium hydroxide. The apparent resistance of legume bacteria to alkali seems to be due to the slight concentration of hydroxyl-ions in the mannitol solution. The highest count was obtained in a neutral solution; small amounts of alkali had very little effect on the number of bacteria. On the other hand, acid in gram equivalent amounts seriously retarded or inhibited growth. The relation of "growth" to "hydrogen-ion concentration" remained almost the same after two and four weeks.

The curves representing the hydrogen-ion concentration of mannitol solution before and after the growth of *B. radiculicola* show clearly that the concentration changes under the effect of the growth of the bacteria, which, apparently, bring about changes in the reaction of the medium favourable to their reproduction.

## 271 - Influence of Position of Grain in the Cob on the Growth of Maize Seedlings.

—HALSTED, BYRON D. and OWEN, EARLE J., in the *Journal of the American Society of Agronomy*, Vol. IX, No. 6, pp. 267-275. Washington, D. C., September 25, 1917.

The experiments were made at the New Jersey Agricultural Station with 5 ears of each of 20 representative varieties and crosses of maize. The grains from each ear were divided into 10 equal lots, each representing a zone of the ear, ranging from the butt to the tip. The average weight of the grains in each zone of 2 of the 5 ears was determined, and 25 kernels from each lot planted 1 inch deep in a greenhouse bed. In the butt and the tip zones, the smallest perfect kernels were chosen; in the others they were taken at random. The plants were harvested 17 days after sowing.

The emergence of the tips of the seedlings was recorded daily and the averages calculated from it. At harvest time the viability, weight and

length of the seedlings were recorded, and the vigour and variability deduced from them. By averaging the 5 units in each set, a series of tables was obtained showing the relationship of the position upon the cob to the following particular characters under consideration: 1) weight of grain; 2) specific gravity of grain; 3) emergence of seedlings; 4) viability of seeds; 5) weight of seedlings; 6) length of seedlings; 7) variability in length. Table I gives information concerning the average weight of the grain, Table II the order of the 7 characters considered; No. 1 represents the minimum, No. 10, the maximum value of the averages

TABLE I. — *Average weight (in centigrams) of grains of 20 varieties of corn in each of 10 zones from the butt to the tip of the ear.*

Varieties	Zone										Average
	Butt									Tip.	
	1	2	3	4	5	6	7	8	9	10	
Longfellow . . . . .	43	44	43	42	42	40	39	37	35	31	39.6

Golden Queen × Cham- pion White Pearl . . .	27	27	26	27	26	25	24	22	20	18	24.2
Golden Queen × Brazi- lian Flour. . . . .	24	24	24	23	23	22	21	21	20	18	22.0
Total	591	593	586	575	565	545	530	508	481	424	
Average	29.6	29.7	29.4	28.8	28.3	27.2	26.5	25.4	24.1	21.2	

Thus, for the general average, with the exception of the butt zone, the weight of the grain decreases from the butt to the tip.

TABLE II. — *Order of the averages for the characters studied.*

Character	Zone									
	1	2	3	4	5	6	7	8	9	10
Weight of grain . . . . .	9	10	8	7	6	5	4	3	2	1
Specific gravity . . . . .	4	5	7	8	9	10	6	3	2	1
Emergence . . . . .	1	10	9	8	6	7	5	2	4	3
Viability . . . . .	1	3	4	10	7	9	6	8	5	2
Vigour . . . . .	2	9	8	10	7	6	5	4	3	1
Length . . . . .	2	3	9	10	8	7	6	5	4	1
Variability . . . . .	10	8	3	5	4	2	6	1	7	9

The *specific gravity* ranges from 1.35 in Golden Queen to 1.16 in Brazilian Flour. The sweet corns have a high specific gravity, due to their low starch and high sugar content and the horny texture of their endosperm. The cross between the two above-mentioned varieties has a specific gravity almost exactly intermediate to the two extremes — 1.26; the other two crosses are also near the mother plant. In a general way the specific gravity decreases in both directions rather regularly from the middle of the ear. If 5 groups are made from base to tip, the totals of the ranking figures are 9, 15, 19, 9, 3. This shows that the decrease is much more rapid in the upper than in the lower half of the ear. If only 3 groups are made, namely, the basal three, the middle three, and the 4 upper zones, the averages of the specific gravities are 1.25, 1.26 and 1.24.

As regards *rapidity of germination* (time between sowing and emergence of the tip), the average for all zones is somewhat less than one week (6.44 days). The butt zone emerged the quickest (a little over 6 days), while the zone just above it took 10 hours longer and was the slowest of all the zones. There was a fairly uniform decrease in time for emergence from the 2nd. to the 10th. zone. This is in correlation with the specific weight, *i. e.* the lighter the grain the more rapid is emergence.

The general average of the *viability* of the grain was 91.91 %, although the unripe ears of Golden Queen only gave 67.87 %, Brazilian Flour 76.94 % and Stowell Evergreen a little more. As has been always observed in previous studies sweet maize, as a group, has the lowest viability. The maximum viability is found in the 4th. zone (94.44 %) ; the minimum in the basal zone (87.68 %), which is closely followed by the tip. The five best zones are the central one and the two contiguous to it on either side. Whereas the heaviest grains are in the lower half of the ear, those of greater density and viability are in the middle zones.

The *vigour* is expressed by the live weight of the plant minus the weight of the grain from which it sprung. For the whole ear the averages of the 20 varieties or crosses tested (see Table I) were (in grams): — 2.277, 3.050, 1.082, 0.356, 2.744, 1.339, 2.374, 2.134, 2.105, 1.911, 1.155, 2.447, 1.098, 1.832, 2.326, 2.198, 1.777, 1.898, 2.272, 1.928; the averages for all the varieties and crosses for each of the 10 zones are: — 1.893, 2.125, 2.116,

2.133, 2.094, 2.064, 2.010, 1.966, 1.896, 1.503; the general average for all the varieties and crosses and for all the zones was 1.980. These results show that, as regards vigour, the best grains are those in the lower half of the ear, with the exclusion of those at the butt, which are very weak. The upper zone shows a uniform decrease in vigour from the 6th. zone to the tip.

There is a strong positive correlation between viability and vigour; the most viable seeds are the most vigorous, and the same naturally applies to the length of the seedling.

Variability is evidently correlated with weakness, but to determine to what degree, measurement of more than 2 500 seedlings must be taken. In other words, viability and vigour are negatively correlated with variability. A set of strong plants is more uniform than one of weak seedlings. Variability is greatly influenced by position on the cob; this may be due to size as well as to maturity and nourishment of the grains.

A practical application of these results would consist in germinating a large sample, say 20 grains, from two rows upon opposite sides near the middle of the ear, selecting ears showing practically 100 % viability, and planting only grains from the middle of the ear, rejecting those from the butt zone and the four upper zones. This would be a more rigorous method than that, now in use, of discarding a few of the grains from the butt and tip of the ear.

272 - **Graft Hybrids Observed on Olive and Maple Trees in Italy.** — *L'Italia agricola*, Year LV, No. 1, p. 17 + 1 coloured plate. Placenza, January 15, 1918.

The coloured plate shows a Cannellino olive tree with white fruit which, when grafted on a Caiazzana olive tree with black fruit, produced white and black olives.

A variegated maple is also reported which, when grafted on a green maple, bore a branch having all the characters of the green maple and none of those of the variegated maple (1).

273 - **The Luleå Branch of the Svalöf Station, North Sweden.** — TEDIN, HANS, in *Sveriges Utisdeförenings Tidskrift*, Year XXVII, Pt. 5, pp. 223-232. Malmö, 1917.

Svalöf and Luleå are separated by more than 10 degrees of latitude, and the physiographical conditions of each differ widely (2), especially where the

PLANT  
BREEDING

(1) For other graft hybrids reported in Italy, see *B. Sept.*, 1915, No. 928. (*Ed.*)

(2) The following facts show the differences between the climatic conditions of the south (Svalöf) and the north (Luleå) of Sweden. It is the custom, which, moreover, corresponds fairly well to reality, to call, in these districts, "summer" the period when the average daily temperature is above 10° C, "winter" the period when it is below 0° C, and "autumn" and "spring", the two intermediate periods. Taking this distribution as a basis, in northern Sweden, summer barely lasts two months, till the middle of August, whereas, in southern Sweden, it begins in the middle of May and lasts to the middle of October, *i. e.*, four months in all. The contrast between north and south is still more marked as regards the growth of cultivated plants if the part of the year free from frosts is considered; at Karesuando (Norland) the last spring frost occurs, on an average, on June 15, and the first autumn frost on August 25, so that the frost-free period hardly lasts 72 days; at Stockholm, on the contrary, there are 4 ½ months without any frost and, in the Island of Ven (Öresund), 6 months. (GUINCHARD, J., *Schweden*, Vol. 1, pp. 43-44, Stockholm, 1913).

growth of cultivated plants is concerned. The aim of the selector is to unite in one variety the characters "intrinsic yield" and "resistance to the most unfavourable meteorological phenomena" in a given locality. As the intensity and distribution of the meteorological phenomena at Svalöf and Luleå differ, it follows that varieties selected at Svalöf do not stand the same chance of success when introduced into Norrland. Experiments on this subject gave absolutely negative results and it was, therefore, decided to form a special centre of selection for the north of Sweden — the Luleå branch Station.

**EARLINESS.** — All crops, especially cereals, in proportion as they grow further south, have a shorter period of growth which allows the plant to attain and exceed the ripening stage during the short summer. What degree of earliness is required for the conditions found in Norrland? It was thought possible to solve this question by using in selection varieties from the northern districts, but it was soon seen that the place of origin is no guarantee of success. Thus, for example, among the barleys grown in the Norrland area early and late varieties. As a whole these varieties answer fairly well to the average climatic conditions and annual variations, but, when separated and grown in pure lines, they may give negative results. The variety No. 01243, a six-rowed barley, isolated at Svalöf from material sent from Luleå, when introduced into Norrland, proved too late, ripening about a week after the local types. Nos. 01201 and 01222, six-rowed barleys from Dalarna (central Sweden), on the contrary, proved in Norrland, as early as the northern types. This may be explained by the fact that every variety transported from one district to another shows a tendency to adapt itself to the new conditions by developing the necessary characters. In southern Sweden the earliest forms of a given type tend to decrease their degree of earliness, or to make it disappear altogether, whereas it is very difficult to show very small differences, of two days for example, differences which, in the north, corresponding to the limits of distribution, are of special importance, for two days more or less for a certain variety may make all the difference between ripening and not ripening.

What has been said for earliness also applies to resistance to cold and diseases.

**CHARACTERS OF THE STRAW.** — In Norrland growth is even more rapid and regular than in the southern districts; the barley No. 01201 which, at Svalöf, has a short stem, when sown in the north has a much longer stem, more subject to lodging. This modification, however, is not equal and proportionate for all varieties. Thus, for example, Findelen No. 0161 and No. 0164 (from plants gathered by the author at Findelen, near Zermatt, Switzerland, at an altitude of about 6890 feet) developed culms of equal length both at Svalöf and at Luleå (length of culm about 2 feet). In order to pass a just opinion on the character of the straw, experiments must be carried out in the district to which the variety is destined.

**GRAIN YIELD.** — The earliness, structure of the culm, resistance to cold and disease, which, as has been seen, vary with the environmental conditions, have a marked influence on the yield, so that even the charac-

ter "productivity" changes in different places. Earliness does not suffice to guarantee the strength of the yield at higher latitudes. A striking example of this is given by the very early six-rowed barley, Svalöf No. 01201. During the years 1894-1904 this barley gave an average of 19.11 cwt. per acre, a yield much below that of the Chevalier variety, 23.57 cwt. per acre. This may be explained by excessive earliness (in the south at least) accompanied almost always by decreased productivity. If, however, 19.11 cwt. are not much at Svalöf, they represent a fairly good harvest in Norrland. Attempts have been made to introduce the barley 01210 in Norrland, but, although it was sufficiently early, the results as regards yield of grain were far from encouraging.

The attempts to introduce into the northern districts types selected at Svalöf go back to 1904, the year in which a series of comparative tests with 37 varieties of barley, 21 six-rowed and 16 two-rowed, was carried out at Luleå.

As regards two-rowed barleys, repeated attempts made even with the very early varieties, such as 0116 from Westergötland, 0161 and 0164 from Findelen (Switzerland), were all completely negative. On the other hand, among the numerous varieties of six-rowed barley studied repeatedly, were distinguished 01209, 01222 and 01225, fairly early and good producers, 01209 at least, also having a large, well-formed caryopsis. The variety 01206 from Dalarne deserves special mention. AXEL ULANDER states that in 1908 this variety was still earlier than the very early native barleys of Joukasförvi and Pasala. In spite of these few exceptions the Svalöf varieties have gradually had to give way before those selected at Luleå, natives of the Norrbotten coast, or the province of Tomeå, or else collected from the Luleå district.

274 - **Experiments in Field Technic in Rod Row Tests.**—HAYES, H. K. and ARNY, A. C., in the *Journal of Agricultural Research*, Vol. XI, No. 9, pp. 399-419. Washington, November 26, 1917.

The lack of uniformity in selection methods sometimes makes it difficult to compare the results obtained by different workers. While the very nature of the investigations excludes the use of exact rules, as in chemistry and physics, it is, nevertheless, possible to standardise the methods so as to decrease errors in the estimation of biometrical data.

Where cereals are concerned, the size and shape of the plots, the competition between them or their reciprocal action, soil heterogeneity, are all factors which have a considerable influence on the yield, and make it difficult to estimate, because many of the figures are not strictly comparable. The authors have attempted to find a method to reduce these sources of error to a minimum by a series of field experiments with barley, oats and wheat, which aimed at determining:—

1) The effects of competition between adjacent rows of cereals of the same and of different varieties.

2) The planning (length, spacing, number of rows) which will most effectually reduce to a minimum the effects of competition.

3) The number of times an experiment must be repeated to eliminate errors due to heterogeneity of soil.

Each of the experimental plots, adjacent one to the other, contained three 18-foot rows of cereals. The rows were 1 foot apart. In other words there were two border rows, one at the left (L), the other at the right (R), and a centre row (C.). This arrangement is shown for one plot in the following figure, which also includes the adjacent rows (A) of the two plots on either hand.

A. — EFFECT OF THE HEIGHT OF THE ADJACENT LINES ON THE YIELD OF THE BORDER LINES OF ANOTHER VARIETY OF THE SAME SPECIES. — There was one plot for each variety, arranged as described above. At harvest time 1 foot was discarded from each row, reducing the length considered to 16 feet.

To compare the *yield in grain* the following method was adopted; — If the left (L) border row yielded more than the right (R) border row, the result was considered *positive* and the difference expressed in + bushels per acre; if the right border yielded the most the result was considered *negative*, and the difference expressed in — bushels per acre.

The height of rows adjacent to the border rows of another plot were compared in the same way. If the variety near the left border was higher than the variety near the right border, the result was *positive*, expressed in + inches and centimetres; in the opposite case the result was *negative*, expressed in — inches and centimetres.

With the results obtained tables were drawn up showing the correlation between *difference in yield* and *difference in height*, such as the following (see p. 306), concerning barley.

The figures given in this table made it possible to calculate (by DAVENPORT'S formula) a very high negative coefficient of correlation:  $-r = -0.519 \pm 0.065$ . The height of the rows of barley adjacent to the border rows of a neighbouring plot thus has a decided influence on the yield in grain of these border rows; the greater this height the lower is the yield.

The same applies to winter wheat, where  $r = -0.337 \pm 0.097$ .

There is, however, but a very slight negative correlation or even a slightly positive relation in oats and spring wheat.

*Correlation between the difference in yield between the border rows of one variety and the difference in height of adjacent lines of other varieties.*

*Difference in yield of a border rows of the same variety (bushels per acre)*

	-9	-7.5	-6	-4.5	-3	-1.5	0	+1.5	+3	+4.5	+6	+7.5	+9	
-25							1			1				2
-20							1		1			1		3
-15								1		1		1		3
-10						1		1	2	1		1		6
-5					1	1	1	1	2	1			1	8
0			1	1	2	1	3		3	2				13
+5	2				2	3		1	1	1				10
+10	1	1					1							4
+15						1			1					2
+20					1			1						2
+25					1									2
+30				1	1									2
	3	1	2	3	8	7	7	5	10	7	0	3	1	57

The figures in the squares within the border represent the number of varieties showing such or such a combination between *difference in yield* and *difference in height*. The totals of these figures for each class are given outside the border on the right and at the bottom and give a total of 57 varieties, shown in the right-hand bottom corner.

B. — EFFECTS OF THE ADJACENT LINES ON THE YIELD OF THE BORDER ROWS OF A DIFFERENT VARIETY OF THE SAME SPECIES. — These effects were determined as in the preceding case. The results show them to be less than the effects produced by the height of adjacent lines. The negative coefficient of correlation was again highest for barley  $-r = -0.394 \pm 0.075$ , about 6 times the probable error, followed by that of spring wheat  $-r = -0.290 \pm 0.087$ . The other cereals had very low *positive* correlations, except in the case of winter wheat, where  $r = +0.315 \pm 0.099$ . These positive coefficients might be due to soil heterogeneity.

C. — VARIABILITY OF BORDER ROWS, CENTRE ROWS AND THREE-ROW PLOTS OF CONTROL PLOTS. — The cereals studied are Haynes Bluestem wheat, Turkey winter wheat, Ligowa oats and Manchuria barley. The border rows were found to vary much more than the centre rows, as the following figures, collected at the Minnesota Plant Breeding Nursery and Farm Crops Section, show,

Cereal	Experiment field	Difference between coefficient of variability of border and central rows
Haynes Bluestem wheat . . . . .	Plant Breeding Nursery . . .	$2.90 \pm 1.788$
	Farm Crops variety test . . .	$1.35 \pm 1.390$
Turkey winter wheat. . . . .	Plant Breeding Nursery. . . .	$2.74 \pm 1.509$
	Farm Crops variety test . . .	$0.94 \pm 1.838$
Ligowa oats . . . . .	Plant Breeding Nursery. . . .	$3.93 \pm 1.230$
	Farm Crops variety test . . .	$2.64 \pm 1.613$
Manchuria barley . . . . .	Plant Breeding Nursery . . .	$10.91 \pm 4.208$
	Farm Crops variety test. . . .	$3.63 \pm 1.386$

The greatest differences are between barley, then between oats; they are but slight in spring and winter wheat.

On the other hand, a comparison between the coefficients of variability of yield between the centre rows and the three row control plots gave the following results: —

*Oats.* — Negative differences, *i. e.* the yield of the centre rows varies less than that of the three-row plots.

*Barley.* — Very slight positive differences:  $-0.55 \pm 2.596$  and  $0.48 \pm 0.993$ .

*Winter and spring wheat.* — Marked positive difference:  $-1.65 \pm 1.313$  and  $2.94 \pm 1.699$  for the first, and  $0.61 \pm 1.215$  and  $2.95 \pm 1.535$  for the second.

In wheat, therefore, the average yield of the three-row plots varies less than that of the centre row, but the difference is not sufficiently great to justify the extra labour which would be required to compute the yield of the two border rows apart from that of the centre row.

From the results obtained the following conclusions were deduced:—

1) There is marked competition between rows 1 foot apart. In selection work, therefore, it is best not to sow only one row per ear, but to sow three-row plots, as the two border rows have a protecting action.

2) In calculating the yield it is unnecessary to consider all the three rows, but time and work may be saved by considering the centre row only as its variability is almost equal to that of the three rows together.

REPETITION OF TESTS IN ORDER TO REDUCE THE ERRORS DUE TO SOIL HETEROGENEITY. — In the experiments described the control plots were

also used to study the efficaciousness of such repetition. Three repetitions reduced error by 25 to 50 % ; 9 to 12, reduced the error to a minimum, making them almost negligible.

**275 - Correlations Observed in Continuously Cropped Barley, in U. S. A. —** See No. 289 of this Review.

**276 - A Method for Determining the Percentage of Self-Pollination in Maize. —** WALLER, A. E., in the *Journal of the American Society of Agronomy*, Vol. IX, No. 1, pp. 35-37. Lancaster, Pa., January, 1917.

In the maize endosperm which results from fusion of the second nucleus of the pollen grain with the two polar nuclei, the yellow colour is dominant to the white. If, therefore, a white variety is fertilised with the pollen of a yellow variety, the resulting ears are hybrid, certain grains having the dominant yellow colour of the male parent, in accordance with the phenomenon called "xenia" (1) by FOCHE.

The author used this phenomenon as an indicator to estimate indirectly the degree of self-fertilisation in maize, applying it as follows: — in a field of yellow corn he placed, here and there, two or three plants of white maize. At the time of tasselling two of the three plants in each hill of white maize were detasseled; the third plant served to measure the degree of self-fertilisation on the basis that the white grains would be self-pollinated, the yellow grains the result of cross-pollination (xenia).

The varieties used were Reid's Yellow Dent and Wing's Hundred-Day White, which are particularly well adapted to cross-fertilisation since they flower about the same time. Of 36 ears, an average of 5.13 % were self-pollinated, but, for the reasons given in § 3, this does not represent the percentage of self-pollination which might take place under field conditions.

It should be remembered that: —

1) It is not always easy to distinguish the white grains from the yellow grains, which may be very pale. This is perhaps due to the formation in the endosperm of only *one set of yellow determinants*, brought by the second nucleus of the pollen grain, as against that of *2 sets of white determinants* contained in the double endosperm nucleus.

2) If, instead of comparing only 2 characters of the endosperm for colour (white and yellow, that is, one pair), the author had compared 2 *pairs* of characters, concerning, for example "colour" and "sugar content", the classification of the grain would have been greatly facilitated. It is, however, difficult to obtain sweet white varieties which flower at the same time as yellow field corn, and to do so a series of plantings would be necessary.

3) In the field the percentage of self-pollination is influenced by ex-

(1) When a female flower is fertilised by the pollen of another variety or species, the resulting fruit may show, in its endosperm, besides the embryo of the hybrid, also the characters belonging to the fruit of the male parent. In his work called *Die Pflanzenmischlinge*, FOCHE calls this phenomenon *xenia*. — See also BAUER, ERWIN, *Einführung in die experimentelle Pflanzenzüchtung*, p. 243. Berlin, 1911. (Ed.)

posure, spacing of rows, the direction and strength of the wind, atmospheric moisture, so that the sources of error can only be eliminated by repeating the experiments during several years.

**277 - The Relation of the Vigour of the Maize Plant to Yield.** — GRANTHAM, A. E., in the *Journal of the American Society of Agronomy*, Vol. IX, No. 7, pp. 340-343. Washington, D. C., October, 1917.

The experiments described were carried out at the Delaware Agricultural Experiment Station, Newark, to ascertain the relation of the vigour of the maize plant to its yield in grain. Of two plants grown in the same hill, one was much stronger and vigorous than the other. About 100 such plants were chosen and grown under identical conditions, the hills thinned, and the stronger plant removed in 50 cases and the weaker one in the other 50 cases.

The two groups were distinguished by: — a) a considerable difference in the date of tasseling (August 5-12), the weaker plants being much later than the others; b) height, measured every 8 days after thinning, from June 25 to September 18. The extreme measurements were: — on June 25, 4.7 and 9.2 inches, and, on September 18, 98.0 and 107.3 inches respectively for the weak and strong plants.

The following table gives the most important results of the experiments: —

*Distribution of ears from strong plants and from weak plants.*

Weight of ear, grams	Number of ears		Weight of ear, grams	Number of ears	
	Strong stalks	Weak stalks		Strong stalks	Weak stalks
0-50	0	5	300-350	11	4
50-100	0	5	350-400	8	1
100-150	2	10	400-450	2	0
150-200	4	9	450-500	3	0
200-250	7	8	500-550	1	0
250-300	8	6			
				46	48

This table shows that strong stalks produce no ears under 100 gm. in weight, whereas, of 48 weak stalks, 10 produced ears weighing less than 100 gm. More than half the ears from strong stalks weighed more than 300 gm., while  $\frac{2}{3}$  of those from weak stalks weighed less than 200 gm. The strong plants are also distinguished by a higher yield in grain (221.7 gm. for strong stalks, 109.6 gm. for weak ones), the weight of the cob (41.7 gm. and 38.8 gm.), and a lower percentage of cob (19 and 24% respectively).

There is, therefore, a positive correlation between vigour and yield (1).

(1) The total weight of the plant is in direct ratio to the total weight of the caryopses (see also FRÜWIRTH, C., *Die Züchtung der landwirtschaftlichen Kulturpflanzen*, 2nd. Ed., Vol. II, p. 9, Berlin, 1909). (Ed.)

278 - Correlations between Ear Characters and Yield in Maize (1). — LOVE, H. H. and WENTZ, J. B., in the *Journal of the American Society of Agronomy*, Vol. IX, No. 7, pp. 315-322. Washington, October 22, 1917.

A summary is first given of the results obtained by workers who, in selection for a given character, chose the two extremes, and sought to establish the relationship between this character and the yield (2). The author then describes his own experiments (at the Department of Plant Breeding, Cornell University, Ithaca, N. Y.) in which he chose, for each character studied, ears near the average type. The maize used was Cornell No. 12, a yellow dent variety selected from the Funk Ninety Day variety. In a table are shown the correlations obtained for all the characters in each of the 5 years during which the experiment lasted.

Below are given, in Table I, the general averages for the characters studied during the 5 years 1910-1914, and, in Table II, the mean percentage of grain in the ears of a few of the highest and lowest classes with the mean yield of these classes.

TABLE I. — *General averages of the characters studied.*

Ear characters correlated with yield per stalk	Average (1910-1914)
Length . . . . . cm.	21.382 $\pm$ 0.045
Average circumference. . . . . cm.	15.278 $\pm$ 0.027
Ration of tip to butt circumference. . . . .	0.859 $\pm$ 0.091
Average circumference of cob . . . . . cm.	9.289 $\pm$ 0.018
Weight . . . . . gm.	273.048 $\pm$ 0.978
Percentage of grain . . . . . %	85.252 $\pm$ 0.073
Average weight of kernels . . . . . gm.	0.283 $\pm$ 0.001
Number of rows . . . . .	17.004 $\pm$ 0.061
Average length of kernels . . . . . cm.	1.314 $\pm$ 0.003
Average width of kernels. . . . . cm.	0.798 $\pm$ 0.003
Yield per stalk . . . . . lbs.	0.727 $\pm$ 0.002

(1) See also R. February 1918, No. 148. (Ed.)

(2) WILLIAMS, C. G. (Corn Experiments, *Ohio Agricultural Experiment Station Bulletin* 282, 1915), selected ears for the maximum and minimum extremes of the characters length of ear, shape of ear, filling of tip, indentation of kernel, weight of ear and percentage of grain. In selecting long and short ears he obtained a difference of only 1.39 bushels per acre in a 10 year average yield in favour of long ears. In selection for shape of ear, tapering ears surpassed cylindrical ears in average yield during a 9-year period by 1.65 bushels per acre. Eight years' selection of bare and filled tips gave an average difference of 0.34 bushel per acre in favour of filled tips. Seven years' selection of rough and smooth dented ears gave an average difference of 1.76 bushels per acre in favour of the smooth type. Seed ears averaging 88.16 % of grain gave a 6-year average yield of 64.61 bushels per acre as compared with 65.06 bushels from ears averaging 76.38 % of grain.

HARTLEY, C. P. (Progress in Methods of Producing Higher Yielding Strains of Corn, *U. S. Department of Agriculture Yearbook*, 1909, p. 309), tabulated the yields of 4 varieties for 6 years, including 1000 ear-to-row tests. He found no relation between the characters of seed ears and yield.

TABLE II. — *Mean percentages of grain in the ears in a few of the highest and lowest classes, with the mean yields of these classes.*

Year	High classes		Low classes	
	Percentage of grain	Yield per stalk, pounds	Percentage of grain	Yield per stalk, pounds
1910 . . . . .	87.074	0.822	81.676	0.859
1911 . . . . .	88.565	0.624	79.375	0.677
1912 . . . . .	87.158	0.672	80.750	0.738
1913 . . . . .	88.447	0.602	80.714	0.847
1914 . . . . .	87.235	0.651	82.750	0.645
<i>Average . . .</i>	<b>87.596</b>	<b>0.692</b>	<b>81.053</b>	<b>0.753</b>

MONTGOMERY, E. G. (Experiments with Corn, *Nebraska Agricultural Experiment Station, Bulletin* 112, 1909), during many years selected ears for the characters shape of ear, shape of kernel and size of ear. He concluded the results were slightly in favour of long ears; the size of the ear depends too much on environment to be of any importance; a medium depth of kernel is to be preferred.

PEARL, RAYMOND and SURFACE, FRANK M. (Experiments in Breeding Sweet Corn, *Maine Agricultural Experiment Station, Bulletin* 183, 1910), carried out, from 1907-1909, a large number of ear-to-row tests with sweet corn. One of their conclusions is that there is no relation between the external seed characters and yield in sweet corn.

SCONCE, H. J. (Scientific Corn Breeding, *Proceedings of the American Breeders' Association*, Vol. VII, p. 43, 1911) tested Reid Yellow Dent and Johnson County White maize for 5 years. He found that ears of these varieties with 18 and 20 rows of kernels gave better yields than those with more than 20 or less than 18 rows. Averaging the results of 4 years he found that, with Reid Yellow Dent, the best yields were obtained with kernels having small germs, and with Johnson County White, with kernels having large germs. In correlating yield with shape of kernel he found that, in both varieties, square-shouldered kernels showing a small space between the rows at the crown and tip gave the best yields.

MCCALL, A. G. and WHEELER, C. S. (Ear characters not correlated with yield in corn, *Journal of the American Society of Agronomy*, Vol. V, p. 117, 1913), of Ohio State University, calculated the correlations between a few ear characters and yield and obtained the following results:

Characters correlated with yield	Coefficients of correlation	
	Series 1	Series 2
Length of ear . . . . .	0.0580 ± 0.0296	0.1017 ± 0.0651
Weight " . . . . .	— 0.0270 ± 0.0292	0.0866 ± 0.0656
Circumference . . . . .	— 0.0968 ± 0.0287	0.1803 ± 0.0636
Density . . . . .	0.0272 ± 0.0293	—

The ears used in this work had not been selected for the characters used in the correlations.

CONCLUSIONS. — 1) The characters, length, ratio of tip circumference to butt circumference, average circumference of cob, weight, average weight of kernels, number of rows of kernels and average length and width of kernels, do not show correlations significant enough to be of value in judging seed maize.

2) There is a slight negative correlation between percentage of grain in the ear and yield, implying that ears containing a low percentage of grain may yield higher than ears with a high percentage of grain.

3) The average circumference of the ear is the only character showing any significant relation to yield.

4) The external characters of the ears cannot serve as a basis for the choice of high yielding ears. The points on a show card are of no value for selecting seed ears, and apply exclusively to show purposes.

5) The only basis for selecting high-yielding seed maize is the ear-to-row progeny test.

LOVE, H. H. (The Relation of Certain Ear Characters to Yield in Corn, *Proceedings of the American Breeders' Association*, Vol. VII, p. 29. Washington, 1912), obtained the following correlations in experiments carried out over two years :

Ear characters correlated with yield per stalk	Minnesota No. 13		Funk Ninety Day	
	1909	1910	1909	1910
Length . . . . .	$-0.099 \pm 0.076$	$0.241 \pm 0.064$	$0.300 \pm 0.061$	$0.058 \pm 0.067$
Weight . . . . .	$0.094 \pm 0.076$	$0.015 \pm 0.068$	$0.323 \pm 0.060$	$0.090 \pm 0.067$
Number of rows . . . . .	$0.260 \pm 0.072$	$-0.127 \pm 0.067$	$-0.061 \pm 0.069$	$-0.034 \pm 0.067$
Weight of kernels . . . . .	—	$0.028 \pm 0.068$	—	$0.043 \pm 0.067$
Ratio of tip circumference to butt circumference . . . . .	—	$-0.162 \pm 0.066$	—	$0.014 \pm 0.067$
Percentage of grain . . . . .	—	$-0.177 \pm 0.066$	—	—

Thus the only characters showing any considerable correlation are length and weight of ear. Of the 8 correlations obtained for these two characters in the two years, two are about five times their probable error, so that these correlations can hardly be considered significant. (See also *B. May* 1912, No. 491).

CUNNINGHAM, C. C. (Relation of Ear Characters of Corn to Yield, *Journal of the American Society of Agronomy*, Vol. VIII, p. 188, 1916), of the Kansas Experiment Station, studied the relation of the ear characters to yield in a number of varieties. He found some variation for length of ear in the different varieties. In the small varieties the long ears yielded a little better than the medium and short ears, but this did not apply to the larger varieties. There was no significant difference in the averages for all varieties. Ears with small circumference out-yielded the large ears. There seems to be no relation between the filling out of the tips of the ears and yield. Smooth ears out-yielded the roughly dented ears. Ears with low percentage of grain yielded slightly higher than those with the higher percentages of grain. Ears with 16 and 18 rows of kernels generally gave the highest yields, though, in this character, there was a difference in varieties.

279 - **Breeding Sweet Corn Resistant to the Corn Earworm.**—COLLINS, G. N. and KEMPTON, T. H., in the *Journal of Agricultural Research*, Vol. XI, No. 11, pp. 544-572. Washington, December 10, 1917.

In the south of the United States and throughout the American tropics the production of sweet maize is greatly hampered by the ravages of the maize earworm (*Chloridea obsoleta* Fab., of the Noctuidae family), which are so serious that, in some districts, the place of sweet maize has been taken by the more resistant field varieties.

In order to unite in a new variety the character "sweet grain" of sweet maize and that of "resistance to earworm" of field maize, a series of hybridisation and selection experiments were carried out from 1912 to 1916 at Victoria (Tex.), Chula Vista, near San Diego (Cal.) and Lanham (Md.). Crosses were first made between the three commercial varieties of sweet corn, Stowell's Evergreen, Early Evergreen and Early Cory, and two varieties of field corn, Brownsville and Marrainto. Brownsville was selected for its resistance to earworm; Marrainto, a variety from northern Mexico, has rather thicker and harsher husks than those of Brownsville. From among the hybrids obtained the four following were chosen:

Ph 75 (Brownsville × Early Cory)

Ph 79 (Stowell's Evergreen × Brownsville)

Ph 77 (Early Evergreen × Brownsville)

Ph 80 (Marrainto × Early Evergreen).

From the beginning of the experiment the four characters considered as important in resistance to earworm were:—

1) *The distance which the husks extend beyond the tip of the ear*; as the larvae usually enter the ear from the tip of the shoot it is advantageous to increase the distance they must travel.

2) *The thickness of the cover of the husk*; as the larvae sometimes enter the ear through holes in the husk a thicker cover might hinder them.

3) *The texture of the husks*; in most sweet varieties the husks are relatively soft and smooth, while in field varieties they are firm and rough, sometimes even covered with firm spicules making their surface like sand-paper. This character might prevent the insects from eating through the husks.

4) *The husk leaves*; it was thought that ears without husk leaves might be less attractive to the moths.

The ears from the  $F_1$  contained a mixture of sweet and horny seeds. In 1914 the sweet seed from selected ears of each of the four above-mentioned hybrids were sown in separate rows at Lanham, one row for each ear. Pollinations were then made of plants of similar appearance, usually within the same row, the characters described being recorded for each plant. Preference was given to plants with long husks and few husk leaves, but other types, including a few that appeared inferior in worm-resistant characters, were not excluded. In 1915, 14 ears were selected and the grain from them sown at Chula Vista, where the earworm does more serious damage than at Lanham.

When the hybrids obtained in 1915 at Chula Vista were compared with other varieties of sweet maize growing in the neighbourhood, the hybrids were found to have suffered less than the other varieties. All condi-

tions being equal, and the effect of competition in adjacent lines (1) being taken into consideration, some lines showed greater resistance than others; thus, the hybrid Ph 124 (Stowell's Evergreen  $\times$  Brownsville) was  $7\frac{1}{2}$  times more resistant than Ph 125 (same cross). This proves that *different plants from the same ear are distinguished by a special degree of resistance.*

In 1916, 35 rows were planted at Lanham, distributed as follows: —

14 rows of the 1915 hybrids.

9 from ears obtained by hand pollinations within the rows of the 1915 row.

8 rows from ears obtained by crosses between the rows in 1915.

2 rows of  $F_1$  crosses between 1915 lines and Hopi maize

1 row of Oregon Evergreen (P 129), a commercial variety of sweet maize

1 row of New Century Wonder (P 125), a commercial soft variety sold as table maize.

The results confirm those of 1915. Ph 124 retained its superiority, showing the character "*resistance to earworm*" to be *hereditary*. Moreover, the degree of immunity may increase from one generation to the other as is shown by the correlation  $0.66 \pm 0.09$  for damage done by earworm. On the other hand, three varieties of sweet maize used for comparison, Oregon Evergreen, one of the most resistant commercial varieties of sweet maize and two Hopi hybrids, Ph 137 and Ph 141, were seriously injured by the parasite.

#### CHARACTERS CORRELATED WITH RESISTANCE: —

1) *Damage*, expressed by a scale from 1 to 10, where 10 expresses complete destruction of the ear.

2) *Number of larvae*.

3) *Damage per larva*.

4) *Prolongation of husk*; the distance from the tip of the ear to that of the husk expressed in centimetres.

5) *Length of ear*.

6) *Length of husks*.

7) *Number of husks*.

8) *Number of layers forming the husk*.

9) *Number of days from planting to silking*.

10) *Maturity*; the proportion of opaque to transparent endosperms estimated in a section of the grain, according to a scale of from 6 to 15; below 6 the grain is not marketable.

11) *Number of days from silking to harvest*.

12) *Husk leaves*; the development is in accordance with a scale of 1 to 10.

13) *Number of rows*.

The correlation of the characters *prolongation, length of husks, number of layers, days to silking, to damage* are expressed by coefficients equal to or above 0.35. There is positive correlation between

*Prolongation and Length of husks.*

*Length of husks and Length of ear*

*Number of husks and Number of layers*

*Number of layers and Days to silking.*

*Days to silking and Maturity, Days from silking to harvest, Husk leaves.*

*Maturity and Days to harvest, Husk leaves.*

These correlations must be borne in mind so that an eventual immunising effect may not be wrongly attributed to one of a pair of correlated characters.

**ANALYSIS OF RESULTS. — Prolongation of husks.** — One of the chief differences between sweet maize and field maize is the greater length of the husks which greatly exceed the lip of the ear in the latter; the larvae of the earworm must thus travel a greater distance to reach the tip. This explains the greater resistance of the field variety. A correlation between *damage* and *length of husk* is, therefore, to be expected. Such a correlation of  $0.71 \pm 0.06$  is, indeed, found, whereas the relation of *regression of damage* (1) to *length of husk* is expressed by the coefficient 1.02, i. e. an increase of 1 cm. in prolongation may save 1 % of the crop. Amongst 14 progeny with an average prolongation of 2.9 cm. there was a loss of 10 %, and among 12 with an average prolongation of 7.7 cm. the loss dropped to 5 %. In other words, an average increase of 4.8 cm. in prolongation was accompanied by an average reduction of 5% in damage (or about  $\frac{1}{100}$  per centimetre).

**Number of layers and number of husks.** — The coefficient of correlation between this character and damage is high — 0.52 — but as only 4.5% of the larvae enter the ear by penetrating the husks, there cannot be said to be any direct relation as to cause and effect between the number of layers and damage. The protective effect of the layers is also partly due to *another character* correlated with thickness which has not been considered in these experiments (partial correlation).

**Husk leaves.** — The larger the leaves the larger the space over which the moth can deposit eggs. The positive correlation between damage and husk leaves is  $0.31 \pm 0.11$ . In selection, therefore, forms with very large husk leaves should be avoided.

(1) When the coefficient of correlation between 2 characters and the standard deviation of each is known the *coefficient of regression* may be easily calculated. For example, to obtain the coefficient of regression of the weight of the ear as related to its length, the coefficient of correlation between *weight* and *length* is multiplied by the standard deviation from the average weight, and the product divided by the standard deviation from the average length, using the formula  $r = \frac{\sigma_w}{\sigma_l}$ , where  $W$  represents the weight in ounces and  $L$ , the length in inches.

Similarly, to calculate the coefficient of regression of the length as related to the weight, the formula  $r = \frac{\sigma_l}{\sigma_w}$  is used. Supposing, for example, that the coefficient of regression of the weight as related to the length is 2.03 and that, in certain groups of ears in a field, the deviation from the average length of the group in relation to the average length of the crop is 2 inches, by multiplying this deviation by the coefficient of regression, these ears may be said to weigh  $2 \times 2.03 = 4.06$  ounces more than the average weight of the ears of the crop.

The coefficient of regression thus gives a specific relation between the standard deviation of 2 correlated characters, so that, if the standard deviation of one of them be known, it is easy to calculate the standard deviation of the other. — Cf. DAVENPORT, E., *Principles of Breeding*, pp. 466-368. (Ed.)

*Number of larvae and damage per larva.* — These values are low in resistant lines. As the number of larvae depends greatly on the degree of attraction of the plant for the female moth, it may be assumed that the plants avoided by the moths are those most distasteful to the larvae. It is probable that this agreement between the instinct of the larva and the moth depends less on the morphological characters of the plant than on chemical differences, probably on the presence of some volatile substance distasteful both to the larva and to the moth. We have, therefore, one of the characters which have not been considered in these investigations, although it is closely correlated with damage.

*Other characters.* — The coefficients of correlation are low and of no importance in practical selection.

**CONCLUSIONS.** — 1) An increase in the length and thickness of the husk covering, and a reduction of the husk leaves increase resistance to earworm.

2) By crossing sweet maize and field maize varieties, the characters "sweet grain" and "resistance of the ears to earworm" may easily be united in one variety in ever-increasing proportions.

**280 - Correlations Observed in Maize Grains, in U. S. A.** — See No. 271 of this Review.

**281 - Inheritance of Abbreviation of Growth in the Cultivated Carrot and Beet.** — DANIEL, LUCIEN, in *Comptes rendus des Séances de l'Académie des Sciences*, Vol. CLXV, No. 25, pp. 1012-1014. Paris, December 17, 1917.

In 1916 the author described his studies on certain nutrition modifications caused by the sea climate and sandy soil in plants transferred from Rennes (Ille-et-Vilaine) to Erquy (Côtes-du-Nord), by the sea (1). He showed that most of these variations were not hereditary, but disappeared with inland cultivation. He extended his observations to the study of the inheritance of other phenomena which appear to be more frequent on the coast, particularly the inheritance of abbreviated growth in carrots and beet, which sometimes give annual plants of no, or of only very minimum, utilitarian value.

(1) DANIEL, LUCIEN, Cultures expérimentales au bord de la mer, in *Comptes rendus des Séances de l'Académie des Sciences*, Vol. CLXIII, No. 18, pp. 483-486. Paris, Oct. 30, 1916.

The author summarised as follows the results of his experiments carried out during 15 years at Erquy: —

1) In 15 years the plants transferred from Rennes to the coast at Erquy, acquired no halophytic characters although subjected to the influence of fog and occasional watering with salt water.

2) The only distinct variations were those caused by the very marked oscillations of the water (quantity, quality and salt content), which caused dwarf and giant plants and all the intermedite stages. This action is entirely transitory, both in the experimental plants themselves and in their descendants. It does not appear to be hereditary so far as can be judged from the negative experiments and their short duration (15 years) as compared with repeated action during many centuries. Giant or dwarf plants, so common on the sea coast according to the degree of moisture at the station, rapidly lose their peculiar characters inland, thus again confirming the non-inheritance of these phenomena.

His experiments, which are still being continued, were carried out simultaneously at Rennes and at Erquy and gave the following results: —

1) The abbreviation of growth is partially hereditary, to a degree varying with the conditions of cultivation in a first generation ;

2) The sensibility to the variation is specific and greater in the variety of carrot studied than in that of beet ;

3) The abbreviation of growth varies with the individual and may be accompanied by unexpected variations showing that the stability of the race has been deeply shaken ;

4) Care must be taken not to use seed of annual carrots and beets ; the mixing of such seeds with pure ones should be suppressed.

282.— The Selection of Some Varieties of Swede Resistant to *Plasmodiophora Brassicae*, in Denmark. — CHRISTENSON, C. I., in *Tidskrift for Planteavl*, Vol. XXVI, Part. 1, pp. 68-82. Copenhagen, 1917.

The English variety Pioneer, of Driffield, Yorkshire, is known to be resistant to the attack of *Plasmodiophora Brassicae*, which causes great damage to swedes in Denmark every year. For this reason, the discovery of two new varieties of swede more resistant than Pioneer to the disease, is worthy of special notice.

One was isolated from the type-variety Klank belonging to the "Trifolium" Society of Copenhagen ; the other came from the Studsgaard Experiment Station. The article describes the results of a series of selections carried out at Studsgaard during 1909-1916, with excellent results. In the autumn of 1908, the author collected 18 healthy, well-developed specimens from plots very badly damaged by *Plasmodiophora*. Some of these choice specimens went bad during the winter ; 11 remained and were planted in the spring of 1909, well isolated to prevent cross-fertilisation.

Sufficient seed was collected from 10 of the plants to allow study of the progeny. The aim was to ascertain whether resistance to *Plasmodiophora* is hereditary. Ten families were named, one for each seed plant: Bangholm Fam. 1, Fam. 2, etc. The seed was sown on plots that had produced swedes for the two previous years that were badly attacked by *Plasmodiophora*. The results for 1910 are given in Table I. The progeny are divided into 3 groups: 1) perfectly resistant ; 2) slightly attacked, but the 'root' retains its form and can be fed to cattle ; 3) badly attacked, the 'root' being completely spoiled. Column 8 in the table shows the degree of intensity of the attack for each family, calculated according to the formula:  $K = \frac{0 \cdot a + 1 \cdot b + 2 \cdot c}{n} \times 10$ , where  $a$  equals the number of unat-

tacked roots,  $b$ , the number of slightly attacked roots,  $c$  the number of badly attacked roots, and  $n$ , the total number ( $a + b + c$ ) of roots.

The progeny of 87 roots, chosen with no criterion of immunity, and crossing under similar conditions, and quite near to the experimental plots, were almost completely destroyed by *Plasmodiophora*: degree of intensity of the attack = 14. The attack was much reduced in the case of the 10 Bangholm families coming from resistant plants; the intensity being 4

(maximum) given by Fam. 1 and 2, and 0.4 (minimum) given by Fam. 4, which was also notable as being almost completely immune.

The 1912-1913 Experiments confirmed those of 1910. During this time, by means of continuous and minute selection in the Studsgaard experimental fields, some lines were isolated that had a high degree of resistance, as was shown by trials in 1914, 1915 and 1916.

Bangholm Pajberg III (ordinary type)	15	194	148	93	450	3	43	33	21

In Table II (1916), in order to find the value of  $K$ , the progeny are divided into 4 groups: — 1) immune; 2) slightly attacked; 3) heavily attacked; 3) almost completely destroyed. The formula  $K = \frac{0.a + 1.b + 2.c + 3.d}{n} \times 10$  is used, where  $d$  equals the number of plants entirely destroyed ( $a$ ,  $b$ ,  $c$  and  $n$  as in the preceding formula).

Among the new forms, Fam. 25 and 19 deserve attention both for high resistance and yield (see Tables II and III). They come close to Fam. 4, which, however, always maintains its first place. This shows the excellent results obtainable by individual selection.

283 — **Flaxwilt: A Study of the Nature and Inheritance of Wilt Resistance.** — TISDALE, W. H., in the *Journal of Agricultural Research*, Vol. XI, No. 11, pp. 573-605, plates 44-46. Washington, December 10, 1917.

The experiments described were carried out in February, 1915, at the University of Wisconsin. Crosses were made between a variety of flax resistant to wilt (*Fusarium lini* Bolley) — North Dakota Resistant 114, designated in the article as No. 4 — with 3 other varieties more or less susceptible to the disease, namely, No. 3, from Dakota, No. 5, with white flowers from Red Wing, Minn., No. 6, from Devil's Lake, N. Dakota., and the behaviour of the hybrids obtained observed.

Only one of the crosses, that between the resistant variety No. 4 and the most susceptible variety, No. 3, gave results which could be explained by a Mendelian formula. The resistant plant was used as female parent, and the progeny designated as 4 D 20, where 4 represents the strain, D the plot on which it was grown, and 20 the number of the female plant. The 26  $F_1$  hybrids thus obtained remained perfectly healthy, whereas the No. 3 control plant wilted entirely. In the  $F_2$ , of 530 plants, 162 were resistant and 368 wilted, giving a ratio which makes it impossible to attribute the character "resistance to wilt" to one single factor. If, however, 4 factors are concerned, these figures (or rather their halves, 81 and 184) are close

to the theoretical figures, 81 resistant to 175 susceptible, corresponding to the Mendelian ratio 1 : 2.16.

However, as has already been said, this cross was the only one the results of which could be explained; in all the others the ratio between resistant and susceptible plants varied so greatly that it could not be accounted for by admitting a constant number of factors. In the  $F_1$  were obtained both more or less resistant plants and very susceptible plants, but, in most cases, intermediate forms, expressed by very varying factors. It must be pointed out that some of the hybrids with the same degree of susceptibility (percentage of dead plants at the end of the experiment) as the susceptible parent plant sometimes showed a marked difference from this parent as to the date of starting, rapidity and duration of the infection; in some plots of susceptible hybrids the first symptom of disease only began to appear when the control parent plants were already wilted to a large extent.

It must be noted that the environmental conditions during the experiments were far from uniform especially as regards the state of the soil, which was sometimes naturally and sometimes artificially infected, thus affecting the resistance of the plants. It seems possible that the complex phenomena observed in these hybridisation experiments may be explained by the specific action of external factors on resistance to wilt. The resistant strain No. 4 was selected to withstand the disease under normal environmental conditions. In this case the factors A, B, C, D, are sufficient to produce immunity, so long, of course, as they are homozygous (AA, BB, CC, DD). When, however, extraordinary conditions (temperature, inoculated soil) favourable to the growth of the parasite are artificially created, the action of A, B, C, D, becomes insufficient, and part at least of the hybrids, resistant under normal conditions, break up into resistant and susceptible plants. In such cases, to regain immunity, other factors, E, F, etc., must be taken into consideration. This has evidently not been done for strain No. 4, selected for growth under normal conditions. The factors in this line may be: — 1) entirely absent, 2) present singly, 3) present in combination, either homozygous or heterozygous. The differences in the results obtained would be thus explained.

The wilting of the plants attacked is due to the combined action of the following factors: — 1) destruction of the root system; 2) use of the food and water supply of the plant by the fungus; 3) more vigorous growth of the fungus and increased transpiration of the host plant due to a rise in temperature; 4) the possible production by the fungus of toxins injurious to the host protoplasm. What is the specific behaviour of the resistant plants towards the pathogenic agent? The mycelium penetrates the root hairs, epidermal cells, the stomata of seedlings, and perhaps also wounds, of both resistant and susceptible plants. In the latter it develops rapidly, killing the tissues, whereas, in the former, it is unable to penetrate the tissues. This may be due to: — a) the permanent chemical composition of the resistant plant may be injurious to the fungus, b) the protoplasm of the resistant plant may be more sensitive than that of the susceptible

plant. thus reacting more readily in the production of the phenomena causing wilting; c) below and around the point attacked the cells of the parenchyma, which form a fourth layer, divide and thicken their walls with a substance giving the suberin reaction; the cork layer thus formed isolates the infected zones, preventing further progress of the hyphae.

284 - **Selection of Pea-seed.** — BEVERLEY, J., in *The Journal of Agriculture, New Zealand Department of Agriculture, Industries and Commerce*, Vol. XV, No. 4, p. 216. Wellington, New Zealand, October, 1917.

The experiments were carried out to ascertain whether the number of peas in the pod has any influence on the vigour and yield of the future crop. The results for the season 1916-1917 were: —

Variety	Number of peas in pod	Plant vigour expressed	Seed yield expressed
B. verley's No 1 pea.	Average: 8 or less	100	100
	Once selected: 10	105	140
	Twice selected: 10	105	156

The results are positive and clearly show the effect of selection. The seed from pods containing 10 produce better developed and more productive plants than those from pods containing 8 or less. The seed from the 1st. generation of pods containing many peas gives a yet higher yield in the 2nd. generation.

285 - **Asparagus Selection in Massachusetts, U. S. A.** — *Twenty-Ninth Annual Report of the Massachusetts Agricultural Experiment Station, Public Document No. 31*, pp. 23-24. Boston, January, 1917.

The asparagus selection work at the Concord Substation, Massachusetts, is in charge of Prof. J. B. NORTON. Starting with the common commercial varieties he successfully isolated strains distinguished, not only by their vigour, and the quality and quantity of their produce, but also by marked resistance to rust (*Puccinia Asparagi* D. C.).

For testing purposes were distributed: — in 1915, to 99 growers, 68 lots of roots of 50 each, and 217 ounce packets of seed; in 1916, to 74 growers, 67 lots of roots of 100 each and 43 ounce packets of seed of the new varieties.

All the reports were favourable, both as regards the produce and the rapidity and vigour of growth. In no case was rust reported, but, in view of the relative freedom from rust attacks in 1915-1916, the results of further tests must be awaited before any definite opinion as to immunity to this disease can be passed.

286 - **Hybrid Chestnuts in the United States.** — MURRILL, W. A., in the *Journal of the New York Botanical Garden*, Vol. XVIII, No. 214, pp. 213-215. Lancaster, Pa., October, 1917.

The paper refers to certain chestnut hybrids obtained and cultivated by Mr. VAN FLEET in his experimental grounds several miles to the north-

east of Washington. The following lines were used for propagation and study: American chinquapin chestnut (*Castanea Chincapin* Hort. = *pumila*), Japanese chestnut (*C. japonica* var. *pubinervis* Makino), and Chinese chestnut (*C. chinensis* Hassk. = *C. sativa*).

CHINQUAPIN × JAPANESE. — Among the hybrids were found all the stages intermediate to the large, sweet chinquapin and the Japanese type with fruit fine, but of poor flavour and good only for cooking. The more chinquapin stock present, the better is the flavour. All these hybrids were immune from chestnut canker or blight (*Diaporthe parasitica* Murr.), and some produced excellent fruit.

CHINQUAPIN × CHINESE. — The use of the Chinese chestnut is to be recommended because of its sweet, soft-skinned nut, much larger than that of the chinquapin. These hybrids, however, are not immune to canker, which sometimes attacks the trees very seriously. It seems best to grow them in shrubs with several trunks, so that, if one is attacked, it may be cut immediately and its place taken by another.

Mr. VAN FLEET's hybrid chestnut plantation covers an area of about 4 acres. The trees are planted at distances of 6 to 8 feet from each other in rows 12 feet apart.

289 - Some Effects of the Successive Cropping of Barley. — GERICKE, W. F., in the *Journal of the American Society of Agronomy*, Vol. IX, No. 7, pp. 325-332. Washington, D. C., October, 1917.

The experiments described, carried out in the Laboratory of Soil Chemistry of the University of California, Berkeley, form part of a study undertaken to investigate the effects of successive cropping of barley on soil in pots under greenhouse conditions. All the factors of production, except the soil, were the same or similar throughout the experiment. Five kilograms of soil were put in each pot, some of which were sown and some

TABLE I. — Yield and ripening, as affected by successive cropping.

Number of crops in one soil	Number of stalks				Period of harvest	
	total per pot	grain producing	producing heads but no grain	producing no heads	first heads ripe	last heads ripe

1 . . . .	29	13	11	5	June 15	July 8
1 . . . . .	40	10	16	14	June 16	July 12

left unsown; so that a series was obtained in which some had produced three crops, some two, some one, and some no crop. Throughout the experiment the culture and water content of the soil was the same for each pot whether it contained growing plants or not. The soil was well supplied with the necessary plant-food constituents and was particularly rich in nitrogen. Analysis by the strong acid digestive method showed it to have the following composition: — insoluble residue, 64.85 %; soluble silica, 9.18 %; Ca O, 2.26 %; Fe<sub>2</sub>O<sub>3</sub>, 45.9 %; Al<sub>2</sub>O<sub>3</sub>, 5.80 %; SO<sub>3</sub>, 0.4 %; Mn<sub>2</sub>O<sub>4</sub>, 0.13 %; Mg O, 0.72 %; K<sub>2</sub>O, 0.62 %; Na<sub>2</sub>O, 0.43 %; P<sub>2</sub>O<sub>5</sub>, 0.48 %; loss on ignition, 11.94 %; total nitrogen, 0.31 %; humus, 3.20 %; nitrogen in humus, 3.30 %.

The seed used was from a very pure strain of Beldi barley. The appended tables show the results of the experiments.

TABLE II. — *Average height in centimetres of the different classes of stalks as affected by successive cropping.*

1 (average of 13 stalks) . .	38.6	15.9	0.665	41.8	40.9	17.2	0.731	42.5

CONCLUSIONS: 1) Plants of the 4th. crop matured with a greater uniformity than those of any other crops. None of them had barren stalks. The number of tillers and barren stalks increased with the plants grown in soil which had produced a lesser number of crops.

2) The total height of all the stalks produced decreased with each successive crop, but the average height of the individual stalks increased with each successive crop.

3) In the 4th. and 3rd. crops the heaviest grain, both in weight per head and in average weight per kernel, varied with the height of the stalks. The tallest stalks produced the largest ears and highest average weight per kernel.

4) In the 2nd. and 1st. crops there was no correlation between the height of stalks and weight of grain per head or average weight per kernel.

290 - Studies on Maize in the United States: Influence of Position of Grain in the Cob on the Growth of Maize Seedlings. — See No. 271 of this Review.

291 - The World's Production of Rice. — See No. 251 of this Review.

292 - The Utilisation of the Civet Bean (*Phaseolus lunatus*) Cultivated in Madagascar. — PRUDHOMME, E. and RIGOTARD, L., in *Feuille d'Informations du Ministère de l'Agriculture*, Year XXIII, No. 5, p. 6. Paris, January 29, 1918.

During the last 15 years the cultivation of the civet bean in Madagascar has increased considerably and it is exported in ever-growing quantities; from 17 700 cwt. in 1910 the exportation has risen to nearly 177 000 cwt.; the 1917 harvest is estimated at 196 800 cwt.

The authors discuss the value of the civet bean as a food. It is particularly appreciated in England, where, under the common name of "butter bean", it is eaten like the ordinary dried bean, and is even considered a choice food.

The authors have recently examined many samples of civet beans at the Colonial Garden. The results of the examination of many varieties confirm the statement that large, flat, white seeds, or those with pink spots at the end or near the hilum, about 22 to 24 mm. long, 13 to 15 mm. wide and 6 mm. thick, only contain from 5 to 7 mgm. of hydrocyanic acid per 100 gm. of seed. The average weight of 100 such seeds is between 115 and 189 gm.

Mr. KOLN ABREST, Director of the Laboratory of Toxicology of the Paris Police Service, supplied the authors with data which prove the civet beans grown at Madagascar to be those of all the numerous varieties of *Phaseolus lunatus* which yield the least hydrocyanic acid. They may be eaten without any danger as is shown by the quantities of acid found on analysis: — 100 gm. of beans of this quality contain barely 2 to 3 mgm. of hydrocyanic acid, if the water in which they are soaked and cooked is thrown away. This amount is harmless to adults.

The sale of the beans should be controlled and the hydrocyanic acid content limited to 10 mgm. per 100 gm. of beans. For this it would be sufficient according to the author's studies, to limit the importation to large, flat seeds, the weight of which varies from 1 000 to 15 000 gm. per 1 000 seeds, either entirely white in colour, or slightly mottled with red or pink.

293 - Winter Potato Growing in the Algerian Sahel. — BESSON, ANTOINE, in the *Bulletin de la Direction Générale de l'Agriculture, du Commerce et de la Colonisation de la Régence de Tunis*, Year **XXI**, No. 90, pp. 22-41. Tunis, 1917.

STARCH CROPS.

In view of the increasing cultivation of the potato in Algeria for export and the absolute lack of sufficiently detailed literature on the subject for the use of the farmer, the author gives information he has been able to collect by his own experiments and numerous observations on the cultivation of the early potato.

To obtain good results planting must be early, which, moreover, allows a second crop of tobacco, maize or red potato. The potatoes may be planted between rows of vines; the cultural methods and fertilisers indispensable to the potato also benefit the vine, and, as the potatoes are lifted before the vine shoots appear the care of the latter can proceed normally.

A detailed study is made of: — 1) choice of land, 2) preparation of the soil, 3) live or dead shelter-hedges, 4) choice of seed (the varieties most to be recommended are: Grenadine or native potato; Royale Kidney hâtive or La Hâtive; Royale Kidney Allemande or Belle de Juillet, harvested in France; Royale Kidney Allemand or Belle de Juillet, harvested in Germany; Flouque de Jersey; Hainaut or Belle de Fontenay); 5) sprouting of the potato, 6) planting, 7) watering, 8) copper sulphate spraying, 9) cultivation, 10) lifting, 11) sorting, 12) fertilisers.

294 - A "Water-Potato". — ROSS, D. M., in *The Journal of Agriculture, New Zealand Department of Agriculture, Industries and Commerce*, Vol. XV, No. 4, pp. 209-210. Wellington, October, 1917.

In the Bay of Plenty district, New Zealand, on the northern bank of the Rangitaiki River, near a fresh water spring, a strong variety of edible potato is found growing amongst watercress (*Nasturtium officinale*). The roots and tubers of the plant are found from 12 to 17 inches below the water. The potatoes are of fair size and ripen as early as August; when cooked they are waxy.

The author sent some of the tubers to the Moumahaki Experimental Farm to see if they could be grown on dry land. Planted on August 31, 1916, they gave vigorous plants with distinct foliage and large blue flowers which bore seed-apples. The crop was lifted on February 6, 1917, and was free from disease. The yield was 12.87 tons per acre, 11 tons of which are marketable (table and seed) and 1.87 tons were pig-potatoes. Boiling tests showed that the potatoes kept their colour well but could not be classed as good cookers. The starch content appears to be high.

295 - Three Fodder Pulses of Bihar and Orissa: Meth, Bhringi and Mashyem Kalai. — GOSH, A. C., in *Department of Agriculture, Bihar and Orissa, An Agricultural Journal*, Vol. V, No. 1, pp. 15-47, 14 tables, 5 plates. Patna, 1917.

FORAGE CROPS  
MEADOWS  
AND PASTURE

A systematic study has been made of the pulse crops grown in the botanical experimental area at Sabour (Bihar and Orissa, India). A botanical description and detailed observations are given of the different varieties, natural crosses, soil, sowing, cultivation, uses, etc.

Some of the most important data on Meth (*Phaseolus Ricciardianus* Ten.), Bhiringi (*Phaseolus aconitifolius* Jacq.) and Mashyem Kalai (*Phaseolus calcaratus* Roxb.) are given in the following table.

	<i>Phaseolus Ricciardianus</i> ( <sup>1</sup> )	<i>Phaseolus aconitifolius</i> ( <sup>2</sup> )	<i>Phaseolus calcaratus</i>
Length of main stem . . . . .	1-2 ft.	1-3 ft.	16-27 inches
Yield } green fodder (average of 3 tests) .	10323 lbs.	3 700 lbs.	10 057 lbs.
per acre } grain . . . . .	523 lbs	—	532 lbs.
<i>Composition of green fodder:</i>			
Water . . . . .	62.73 %	50 %	70.29 %
Albuminoids . . . . .	5.02	6.94	3.97
Amides . . . . .	1.53	1.13	0.93
Crude fibre . . . . .	3.18	4.25	3.42
Ash . . . . .	5.11	8.91	3.42
Silica in ash . . . . .	1.65	4.88	0.93
Digestible carbohydrates . . . . .	22.43	28.77	17.97
<i>Composition of unhusked seed:</i>			
Moisture . . . . .	8.10 %	8.65 %	( <sup>2</sup> ) 9.85 %
Ether extract . . . . .	0.50	0.68	0.38
Albuminoids . . . . .	21.52	22.38	20.12
Nitrogen in albuminoids . . . . .	3.46	3.58	3.27
Crude fibre . . . . .	6.38	3.88	4.33
Digestible carbohydrates . . . . .	59.62	60.59	60.61
Ash . . . . .	3.87	3.83	4.33
Silica in ash . . . . .	0.07	0.07-0.1	0.002-0.003

(1) Yellow seed variety. — (2) Black mottled seed variety.

USES. — *Ph. Ricciardianus*. — Chiefly grown for green fodder. The seeds, though indigestible, are used as human food; entire or partly crushed seeds steeped in water overnight are given to cattle and horses. The straw and husks are used as a food for cattle.

*Ph. aconitifolius*. — The seed is used for human consumption. The pod husks and straw are fed to cattle.

*Ph. calcaratus*. — Grown particularly for green fodder. The seed, if first baked and crushed, may be used for human consumption.

296 - Grass Experiments at Hawkesbury Agricultural College, 1916-17. — KERLE, W. D., in *The Agricultural Gazette of New South Wales*, Vol. XXVIII, Pt. 2, pp. 809-813. Sydney, November, 1917.

The year ending June 30, 1917, was exceptionally dry. The rainfall was 29.610 inches, nearly half of which fell during the three months October-December.

The experiments were divided into two series: 1) rows of 116 links in length and 2 1/2 feet apart, 2) field plots of 1/4 acre.

The first trials, besides their use for study and instruction, had as aim, a) to determine the suitability to the district of the common native and intro-

duced grasses; b) to determine the value of newly-introduced grasses; c) to improve varieties by selection.

The second trials aimed at: — a) testing under ordinary field conditions those varieties which had given good results in the row trials; b) to establish seed reserve areas, the seed of the best plants being distributed to the farmers for testing. The soil was a light volcanic loam of comparatively uniform composition.

ROW TRIALS. — Three new grasses were tested: *Pennisetum massaicum*, *P. tristachya*, and *Setaria nigrirostris* (South African Pigeon Grass). The first proved worthy of further trials. It stooled well, resisted several severe frosts in early winter, grew to a height of 2 ½ feet, but was eventually destroyed by a succession of very heavy frosts. The second, a native of Brazil, did badly. The third stooled well, grew strongly in autumn and reached a height of 5 ½ feet; it, however, gives a coarse fodder and is killed by frost.

Field trials. — As the row trials, these were started in 1913.

In 1913 were grown: —

*Eragrostis curvula*, var. *valida* (a Love grass) — *Andropogon intermedius* (Rare blue grass) — *Eragrostis leptostachya* (Paddock Love grass) — *Paspalum dilatatum* — *Chloris Gayana* (Rhodes grass) — *Anthistiria avenacea* (Tall Oat grass) — *Bromus inermis* (Awnless Brome grass) — *B. unioloides* (Prairie grass) — to which were added: in 1914; *Pollinia fulva* (Brown Top grass or Sugar grass); in 1915; three new strains of *Bromus inermis* — *Phalaris bulbosa* (Toowoomba Canary grass); in 1916: *Schedonorus Hookerianus* (Hookers Fescue) — *Festuca arundinacea* (Giant Fescue) — *Pennisetum purpureum* (Elephant grass or Napier's Fodder grass) — *Andropogon Sorghum* var. (Sudan grass); in 1917: *Deyeuxia coarctata*.

*Eragrostis curvula*. — Gives a coarse fodder unsuited to cattle in New South Wales; discarded.

*Andropogon intermedius*. — Growth good; height 3 ½ feet; yield 3 tons 18 cwt. per acre; gives the highest yield of succulent forage of any of the New South Wales native grasses. Its chief merits are: — drought resistance, succulence, palatableness to stock, free seeding.

*Eragrostis leptostachya*. — A native grass; reaches a height of 2 ft.; very hardy; seeds freely; bears heavy stocking, average yield, 2 ½ tons per acre.

*Paspalum dilatatum*. — Considering the wetness of the beginning of the season, this plant grew and produced excellently (height 5 ft., yield 6 tons, 2 cwt. 3 qrs. per acre); in dry seasons it hardly grows at all, and therefore, can not be recommended.

*Chloris Gayana*. — Average height 4 ft., yield of forage 5 tons 5 cwt. 2 qrs. per acre; growth fair in both dry and wet seasons, but not readily eaten by stock because of its sour taste.

*Anthistiria avenacea*. — Native; drought resistant; height 5 ft. 3 in.; yield of greenstuff 5 tons 1 cwt. per acre; not to be recommended on account of its coarseness and poor seeding capacities.

*Bromus inermis*. — Height 2 ½ ft.; yield of grass 3 tons 5 cwt. per acre; is not well adapted to the coast, but does well in the northern and central Tablelands, and in the irrigation area.

*Bromus unioloides*. — The plot sown in 1913 has always given excellent harvests; the variety, normally annual, has there become perennial. Merits: — resistance to frost, free seeding habit, palatableness. Chief defect: — inability to withstand heavy grazing.

*Pollinia fulva*. — Native; height 3 ft. (rare); yield of greenstuff 4 tons 2 cwt. per acre; tender, relished by stock.

*Phalaris bulbosa*. — Height 5 ½ feet; yield 7 ½ tons per acre; fodder tender, easy to harvest and thresh; excellent hay; grain has high percentage of germination; resistant to cold, but only slightly so to hot, dry summers; the best winter and spring grass tested at Hawkesbury.

*Schedonorus Hookerianus*. — Native; drought and frost resistant; adapted to high districts; grows little, fodder coarse.

*Festuca arundinacea*. — Grows little; fodder coarse.

*Deyeuscia coarctata*. — Promising; fodder tender.

*Pennisetum purpureum*. — Great growth and very high yield, height 10 to 11 feet with 60 to 80 stalks per stool, 21 tons per acre; does not set seed, but is easily propagated by cuttings or roots; dairy cows eat the whole plant when it is chaffed, but otherwise only the leaves.

*Andropogon sorghum*. — It gave two harvests during the year, yielding a total of 6 tons 10 cwt. 0 qr. 15 lb.; a plot grown for seed threshed at the rate of 623 ½ lb. per acre. It gives a higher yield than Hungarian millet (*Setaria italica*); resists summer drought; grows rapidly; is specially suited for a hay or soiling crop. Of all the grasses tested at Hawkesbury this is the best adapted to dry climates, and, under normal conditions, is superior to the others as a hay or soiling crop.

## FIBRE CROPS

297 — *Wrightia annamensis*, a Textile Fibre Plant of Indochina. — See No. 348 of this Review.

## HORTICULTURE

298 — **Strawberry Growing in the United States.** — DARROW, GEORGE, M. — I. Strawberry Culture in Tennessee, Kentucky and West Virginia. *U. S. Department of Agriculture, Farmer's Bulletin* 854, pp. 24, 11 figs., bibliography. Washington, August, 1917. — II. Everbearing Strawberries. *Ibid.* No. 901, pp. 19, 7 figs. Washington, November, 1917.

I. — Strawberries are very largely grown, both intensively and extensively, in Tennessee, Kentucky and West Virginia. Intensive methods are the best suited to the district. The author deals with the following points: — choice of farm; choice of field; preparation of soil; fertilisers (acid phosphate and steamed bone meal are most commonly used, being applied at the rate of 200 to 800 lbs. per acre; stable manure should only be applied to crops preceding strawberries); planting (at intervals of about 3 ft. in rows 3 ½ ft. apart; the distance between the plants should be reduced to 18 inches if there is any danger of the plants' being killed by insect larvae or drought; after hoeing, the ground is usually covered with straw while the plant is growing); methods of cultivation.

The Klondike variety is that most extensively grown in Tennessee. The Aroma is found especially in the north of this State; round Nashville, Gandy is preferred. In Kentucky, Aroma is considered the best variety, but in heavy clay soils Gandy is considered best. In other parts of Ken-

tucky and in West Virginia the chief varieties grown are Gandy, Aroma and Dunlap.

II. — Most of the European everbearing strawberries are descended by hybridisation from the Alpine strawberry. The American everbearing strawberries, however, are derived from a plant bearing flowers and fruit in all the stages of its development, found by Mr. SAMUEL COOPER in 1898 among plants of the Bismarck variety, considered to be a cross between the Van Deman and the Bubach varieties. Mr. COOPER named this plant Pan American, and from it he obtained other varieties bearing fruit till autumn; amongst these may be mentioned: — Autumn, Productive, Superb (the widest known and the best), Peerless, Onward, Forward and Advance. The value of the last four has not yet been determined, but Peerless seems to have characters superior to those of Superb.

Mr. HARLOW ROCKHILL of Iowa has obtained many everbearing plants by crossing the European variety, Louis Gautier, with the Pan American and other varieties which normally only bear fruit in early summer. The best known of the varieties thus obtained is Progressive (Dunlap × Pan American); mention may also be made of the varieties Iowa and Standpat (both derived from Pan American × Dunlap). Other varieties, the value of which has not yet been determined, have been obtained by different workers, especially at the Minnesota Agricultural Experiment Station.

The characters and adaptation to different parts of the United States are first examined, and the following points then discussed: — soil; time and method of planting; cultural methods; harvesting; yields. East of the Rocky Mountains the Superb variety is less productive than the Progressive, but, under favourable conditions, over 1000 quarts per acre may be obtained in summer and autumn. In the irrigated districts of Idaho, Oregon and Washington, where the conditions seem more favourable to this variety, the yields are higher. The early summer crop of Superb is generally larger, with bigger berries, than that of Progressive. The varieties of everbearing strawberries now on the market are: — Advance, Americus, Autumn, Forward, Francis, Iowa, Onward, Pan American, Peerless, Productive, Progressive, Standpat and Superb. The Superb and Progressive varieties are most widely grown. Another variety, obtained in 1910 — Minnesota No. 1017 — distributed by the Minnesota State Horticultural Society, has been introduced on to the market. It is very vigorous and very productive, with globular, dark red, firm berries of excellent quality. Although grown in Minnesota and the neighbouring States, this variety is not to be recommended at present for general planting because, in certain districts, it has been found to show but slight resistance to cryptogamic diseases.

299 — **Raspberry Culture.** — DARROW, GEORGE M., in the *U. S. Department of Agriculture, Farmer's Bulletin* 887, pp. 44, 33 figs. bibliography. Washington, October, 1917.

In the United States the raspberry is grown, not only in small plantations for the home and local market, but, in some districts, as the principal commercial crop. Statistics show that, in 1909, there were 48 668 acres of raspberries in the United States.

The methods of cultivation on estates which specialise in raspberries are very progressive. Detailed information is given on: — choice of plantation; preparation of the land; planting (there are 3 methods of planting — 1) the hill system, in which a horse cultivator is used on all sides of the plant; 2) linear; 3) hedges, where the cultivator is used in one direction only); manuring (an average of 10 tons per acre of stable manure, leguminous cover crops to be dug in as green manure); training and pruning; winter protection.

The yields vary greatly according to the variety grown, the methods used, and climatic conditions. In New York the average yield is from 1 300 to 1400 quarts of red raspberries per acre. In Colorado, the Marlboro' variety, if well protected during winter, will yield over 4 000 quarts per acre. In the Puyallup Valley (Washington), fields of Cuthberts properly cared for will yield 6 000 quarts per acre, and the Antwerp, 8 000 quarts per acre.

The best varieties now grown are: —

**RED AND YELLOW VARIETIES:** Antwerp, Cuthbert, Eaton (including the varieties Idaho and Iowa), Empire, Golden Queen, Herbert, Junc, King, London, Marlboro', Miller, Ohta, Perfection, Ranere (St. Regis variety), Ruby, Sunbeam, Superlative, Surprise, Welch.

**PURPLE VARIETIES:** Cardinal, Columbian, Haymaker, Royal (Royal Purple variety) Shaffer.

**BLACK VARIETIES:** Cumberland, Farmer (Plum Farmer variety), Gregg, Hoosier, Kansas, Ohio, Older, Pearl (Black Pearl).

A large part of the raspberry crop is marketed in the fresh state. The Census Bureau estimated the value of canned raspberries in 1914 to be \$1 137 207.

#### FRUIT GROWING

300 — **Citrus Cultivation in Surinam.** — LIEMS, J. A., in *Department van den Landbouw, Suriname, Bulletin* No. 35, pp. 29 + plates. Paramaribo, November, 1917.

There are many orange trees scattered about the plantations in Dutch Guiana, but orange groves have only been formed there more or less recently; the first, planted at Vredenburg, contained 142 trees. Near Surinam is a nine year old grove covering about  $4\frac{1}{2}$  acres, and another covering nearly 34 acres, composed of native citrus trees from 3 to 8 years old. Other groves have been planted near the Commewyne River. In order to increase the cultivation of citrus trees the Department of Agriculture of the Colony has recently distributed, amongst small holders, a large quantity of grafted orange trees. Of all tropical fruits the orange is the best adapted to export. Exportation was begun in 1907 and, since then, the local Department of Agriculture has shipped oranges and tangerines to Holland. From the point of view of the prices obtained the results were encouraging. In 1909, 0.24 d. was obtained per orange sold in Holland; in 1910,  $\frac{1}{2}$  d., in 1914, 0.36 d. In 1911, as a result of delay in the departure and voyage of the boat carrying them, the oranges arrived in an unsaleable condition. In 1912, as the crop was poor, no fruit was exported. The experiment was a complete failure in 1913 as a result of the unfavourable shipping conditions. As the boats were not suitably fitted for carrying oranges, a large number of damaged fruit was found in all the shipments to Holland. According to the author, there is no doubt that, when normal con-

ditions prevail again, the shipments may be re-started under conditions favourable to the keeping of the oranges during transport, so that a better price will be obtained for the fruit exported. In Surinam the oranges ripen from July to October, the months during which they are absent from the European market. As Surinam oranges are larger and of better flavour than European ones, they are much in demand on the Amsterdam and Dutch inland markets.

The rules to be observed in sowing seed, care of the seedlings in the nursery, grafting, final plantation (in squares, 25 feet apart, or about 70 trees per acre), cultural methods, etc. are given.

The chief disease is gummosis, found in groves where the trees are too close together. The chief injurious insects are ants, which greatly damage the orange trees, and scale insects, which attack particularly young nursery plants.

As the cultivation of orange trees is relatively recent in Surinam, it is too early to state which foreign varieties are to be recommended. Lambs Summer variety produces, in sandy soil, good fruit much appreciated in Europe, but which ripens a little late. The Washington Navel orange is less good and less juicy than the native fruit. The Director of the Botanical Garden and the author have sought the best varieties for propagation among the native varieties.

A yield of 1000 fruit per adult tree is not exceptional. At Vredenburg in 1911, a tree gave 3 800 fruit. The average yield per tree may be placed at 500 fruit. Estimating the sale price at  $\frac{1}{4}$  d. per orange, an acre of 65 trees with an average of 500 fruit would bring in about £ 40; from this must be subtracted the cost of cultivation, placed at about £ 4.

The methods of packing are described, those used in California for shipping oranges being specially recommended.

301 - The Nigerian Lime Tree (*Citrus medica* var *acida*). — See No. 254 of this Review.

302 - The Cultivation of the Pistachio Tree. — See No. 254 of this Review.

303 - Hybrid Bearers in 1917 in France. — PÉB-LABY, F., in *La Vie agricole et rurale*, Year VII, No. 32, pp. 103-106; No. 36, pp. 170-173. Paris, 1917.

VINE GROWING.

In view of the ever increasing damage caused by cryptogamic diseases in the vineyards, the use of hybrid bearers becomes essential, and it is advisable to plant them without hesitation. The principal hybrids, new and old, are described with special reference to their behaviour in 1917, especially in the author's experiment plot at Toulouse.

I. — BEHAVIOUR OF SOME OLD HYBRIDS. — Seibel Nos. 1020, 156, 128, 1077. The attack of black rot which occurred during the first days of June had no serious effect on these four hybrids. There were a few patches on the leaves, and very little on the pedicel of the bunch. None of them spread on account of the prolonged drought and heat. Some French plants, such as *Portugais bleu* and *Grand noir* suffered rather badly in Bas-Languedoc; in Armagnac some districts were seriously affected by this disease. Only in

some badly exposed rows were blisters causing loss of grapes on the bunches of 1020, 128 and 156. These three hybrids gave excellent crops.

Mention must be made of 128 on account of its remarkable behaviour in 1917, with goodsized fruit. The plants, which had been attacked by black rust two years before, and had given no harvest since then, gave a particularly heavy crop without any treatment whatever. The two stocks which suit it best are 3306 and *Rupestris du Lot*. In the experiment plots at Toulouse it does as well direct as grafted.

As usual 1020 yielded well, perhaps better ungrafted than grafted. Except a few badly exposed plants which suffered from mildew and oidium, they were all healthy with yields which varied according to the stock. In 1917, the stocks which appeared to suit it best were 34-E and 3306.

There is nothing of particular interest to be noted for 1077, which behaved as usual. It must be noted that this hybrid, known to be sensitive to black rot, showed no patches on the clusters as the others did. This is probably because it was grown in a more airy, sunny place with a better exposure.

These four hybrids have never been treated with sulphate or sulphur during the ten years since they have been planted. There is no doubt that, had they been treated with copper or sulphur, they would not have suffered from the attacks mentioned, or only to a very slight extent.

*Seibel 138*: — An excellent plant, either direct or grafted. The lace-like patches of mildew on its leaves never attack the grapes and do not prevent them from ripening; if it does not yield heavily it at least yields regularly.

*Seibel 1003*: — has never failed to give a crop of medium sized grapes; it suffers more from lime than from mildew.

*Seibel 2*: — always gives a regular and good yield; suffers very little from mildew; does well with *Riparia* as stock.

*Seibel 1000*: — did very well as in the preceding years, but lost part of its fruit as a result of black rust; the harvest was reduced by half; neither the soil nor the climate of the Toulouse Garden suit it; but it does very well elsewhere, especially in the south.

*Seibel 1070*: — does very well in good exposures; always has a heavy crop; suffers from oidium, but one or two good sulphurings protect it.

*Couderc 7103*: — has the same fault and needs the same treatment; gives a fairly good yield; not too sensitive to mildew.

*Couderc 7104*: — showed its usual good and bad qualities; lacks vigour when ungrafted and with most stock; it gives a small harvest but excellent grapes.

*Couderc 7120*: — always the same, suffers from no disease and gives an average, but regular, harvest; produces better in the south than in the south-west.

*Couderc 4401*: — its principal fault is that it suffers from oidium and black rust; in the author's garden, part of the crop is lost each year as a result of this last disease; elsewhere, if well tended, it produces well and without non-setting.

*General 157*: — ~~white~~, is placed among the old hybrids because, in spite

of its faults, it is found everywhere at the present time; it is fairly liable to mildew and not resistant to oidium; in 1917, as in preceding years, the leaves which had not been sprayed with sulphate were attacked, but there was neither grey rot nor red rot on the clusters; it is in demand everywhere because if treated with sulphate and sulphur its heavy yield (about 9 to 13 lbs.) is assured.

It is seen that among these old hybrids are some good ones, which, in the absence of others, might be used, for 128, if well exposed, 156, and Nos. 2, 138, 2003, 1070 and 7120 always give relatively good yields, especially if treated once or twice with copper and sulphur. *Girerd* and 1020 are now appreciated everywhere. There are, however, more recent hybrids which are justly considered superior to the preceding ones by reason of better grapes, a greater resistance, and absence of certain faults, recognised by those who grow them or make wine with them.

II. MORE RECENT HYBRIDS. — A. BLACK HYBRIDS. — (Untreated with copper and sulphur)

*Seibel* 753 : — has just a few small unimportant spots of mildew on its leaves, the grapes are intact, of good size, well-spaced; very regular.

*Seibel* 873 : — resists mildew well, did not suffer in 1917 either on the leaves or fruit, which is large, close and almost average.

*Seibel* 4121 : — remarkable for the resistance of its leaves and its clusters; the author has never seen the slightest sign of disease on it; bears a good crop, and, although its fruit is not very large it gives 13 lbs. or more per plant; neutral wine, strongly coloured, giving, in 1916, 9.6°; strong plant, doing as well ungrafted as grafted; bushy.

*Seibel* 4643 : — only has a few negligible spots of mildew on its leaves; grapes intact, fairly long, not very close, excellent, sweet, giving a first class wine; rather similar to French plants.

*Gaillard* 194 : — completely immune to mildew in the Toulouse Garden; elsewhere it is said to suffer slightly from this disease; in the Toulouse garden it is more vigorous direct than grafted, and to such an extent that the grapes did not all set; must be carefully pruned to avoid loss of the many grapes; ripens early; wine much appreciated.

*Jurie* 580 : — has the appearance of a stock plant with hardy leaves; barely subject to mildew; gives a heavy yield in good soils; very strong, does as well grafted as ungrafted.

*Malègue* 829-6 and 1551-2; liable to black rust which excludes them from certain damp districts; it may be protected from mildew by one or two sulphate sprayings; the second is rather later than the first; very good wine.

In this group of black grapes, *Seibel* 4121 and *Jurie* 580, are noted as particularly hardy; the two *Malègue* mentioned, as finer and almost equally good yielders.

B. PINK HYBRID : — *Seibel* 2859 *rose*; resistant to mildew without sulphate spraying; good yielder; good wine.

C. WHITE HYBRIDS. — This group includes plants valuable both for their resistance to disease and their produce.

*Seibel* 793 : — highly recommended on account of its great resistance

to all diseases ; if the grapes and seed are not very large, there is at least the certainty of an annual harvest, without non-setting, of good flavour, without the expense of copper or sulphur.

*Seibel 850* : — less resistant than the preceding one, but can do without sulphate treatment in years such as 1917; resisted well in the author's experiment plot ; fruitful ; average clusters with average grapes.

*Seibel 880* : — can, if necessary, do without sulphate spraying ; good and regular yielder, giving excellent grapes, but often below the average ; appears to be derived from 2 red parents — 28-112 and 2003.

*Seibel 867* : — fine, cylindrical cluster, winged, fruit above the average, does not suffer from non-setting or other defects ; may be said to be immune to all diseases ; wine said to be slightly foxy, which is not surprising as the plant is descended from 2003 and *Noah*, but is much less foxy than wine from *Noah*.

*Seibel 2653* : — valuable as a table grape in the absence of *Chasselas*, so long as it does not abort too much ; its chief fault in some years is liability to non-setting in certain districts ; not so subject to mildew as *Chasselas* and is satisfactorily protected against strong attacks by two or three sulphate sprayings ; fruit big, oval, and excellent, not subject to oidium.

*Seibel 4773* : — like 793 it is immune to all diseases, but gives a higher yield ; its wood and veins are also red, especially when growth begins, longer fruit rather wider apart ; very sweet juice.

*Seibel 3021* : — very slightly subject to mildew ; without ever having been treated with sulphate it lost no leaf through this disease ; grapes only average, or below the average, close-set and of good flavour, ripen in the second late period.

*Seibel 4681* : — has still better foliage ; cannot do without copper and sulphur ; yield below the average because fruit is below the average ; wine of good flavour and alcoholic.

With the exception of No. 2653, which requires two or three sulphate sprayings, all the other white hybrids can do without sulphate. If they do not give a high yield of 22 lbs. per plant they give a regular average yield of good-flavoured grapes, except 867 which is slightly foxy, and a wine rich in alcohol which may be used either alone or mixed, and is of great value for blending wines.

*Couderc 235-120* and 272-60 ; the first yields well and is easily protected ; the second is subject to oidium.

*Malègue 1157-1* and 1897-12 ; do well in the Toulouse district with an average of two sulphate sprayings ; a fairly large quantity of grapes above the average, ripening in the second late period, excellent wine ; the first is slightly subject to mildew.

III. NEW HYBRIDS. — These hybrids have been grown *directly* in the experiment garden since 1914 ; they are at their third leaf. They have also been grafted on various stock, and put in next to the direct plants the following year. None have been treated with copper or sulphur ; the square on which they are grown is about 9 yards from a *Chasselas* vine which was sprayed four times and eaten up by mildew. Round the edge of the plot

are hybrids which lost almost their whole harvest through mildew, black rot and oidium. Although the hybrids of this collection are not entirely immune to disease, they suffer less than the older ones. Their relative resistance may be seen at a glance and an ascending or descending scale easily constructed. For the vine-grower their value lies in the comparisons which may be made between the relative quality of about 60 hybrids grown side by side under identical cultural conditions and without any treatment.

The most important are :

*A. WHITE HYBRIDS* : — *Seibel* 4657, direct ; large leaf, wide, with shallow lateral sinuses ; large widely-spaced, very pointed teeth at edges, more marked than those of the muscatel, dark green, dull ; internodes from 13. to 15 cm., green, not red ; bunches large, branchy, loose, with oval fruit above the average, fairly far apart, ripening at the end of the first period, of good flavour and very sweet ; may be regarded as a table and vat grape ; very fruitful ; does not appear to be subject to non-setting, and is, consequently, a good yielder ; with neither sulphur nor sulphate treatment it only had a few insignificant spots of mildew on some of its leaves.

*Seibel* 4986 : — direct ; very vigorous ; leaves with deep sinuses and rounded at the base, very large, very pointed shiny teeth, set far apart ; long internodes of 17 to 20 cm ; bunches, mostly winged, cylindrical-conical, with round, fairly close fruit, average or above the average, ripening at the end of the first period ; good flavour ; very productive, does not non-set, thus giving a good yield ; very resistant to mildew and oidium.

*Seibel* 4633 : — direct ; best yielder of the whole collection ; excellent leaf of an almost dark green, shining as if varnished ; lateral sinuses absent, those preceding the tip, fairly marked, giving the leaf a round appearance ; teeth fairly wide and regular, internodes 9 to 10 cm. long, of green, thick wood ; very fruitful ; bunches above the average with round fruit, above the average, close, ripening in the second period, good flavour, almost perfect resistance, subject to neither mildew, oidium, nor black rust.

*Seibel* 4603 : — direct ; the lower leaves are dark green and cut out like those of a fig tree, the sinuses being shallow but the teeth round them well marked ; internodes 9 to 10 cm. long of green wood ; clusters cylindrical or fairly conical, with round, average, close fruit of good flavour ; very resistant to mildew.

*Seibel* 4955 : — direct ; leaves have hardly any sinuses and appear round, of the green of *Rupestris* and of average size ; internodes relatively short of 7 to 8 cm ; wood green ; very fruitful ; bunches cylindrical, usually above the average, with fairly close, round, average fruit ; a very few patches of mildew on the leaves.

*Seibel* 5279 : — direct ; leaf appears round and is only pointed at the base, where there are two shallow sinuses ; teeth few but fairly pointed ; tissue, slightly leathery as that of the Noah leaf ; internodes from 6 to 9 cm. ; wood green ; very fruitful ; clusters average, rather long, wide at the base, above the average ; fruit close, round, average, ripens early, end of August, grape sweet, excellent, remains a long time on the bunch and is a good keeping grape ; strong resistance to oidium and mildew.

*Seibel 4709* : — direct ; leaves long with normal sinuses, slightly pointed teeth, of a dark green colour ; internodes fairly large, from 8 to 10 cm., wood green ; very productive, clusters average, not very long, squat ; grapes average or above the average, round, close, of excellent flavour ; ripening during the first period ; very resistant to disease, barely a few spots of mildew in autumn.

B. RED HYBRIDS. — *Seibel 4015* : — direct ; leaves large and heart-shaped, without pronounced lower sinuses, teeth fairly prominent ; wood of shoots green ; internodes from 12 to 14 cm. ; very fruitful and, on account of its average clusters with average, round fruit, very productive ; ripens during the second period ; foxy flavour, which is its only fault ; remarkable resistance to disease.

*Seibel 4565* : — direct ; leaf large, wider than it is high, round, no sinus, large teeth ; seems fairly hardy ; wood green ; internodes average from 8 to 9 cm. ; very fruitful and productive ; cluster conical, long, above average ; fruit average, fairly close, round, ripening during the first period, slightly pulpy ; fairly good resistance to disease.

*Seibel 5145* : — direct, average leaf, round, with appearance and red veins of the Berlandieri leaf, without well-marked teeth ; wood red ; internodes fairly long, 10 to 12 cm. ; good producer ; clusters above the average, long and sometimes winged, fruit average, round, juicy, ripening during the second period ; excellent resistance to disease.

## LIVE STOCK AND BREEDING.

### HYGIENE

304 - **Screw-Worms and other Maggots Affecting Animals.** — BISHOP, F. C., MITCHELL, J. D. and PARMAN, D. C., in *U. S. Department of Agriculture, Farmers' Bulletin* 857, pp. 20, 8 figs. Washington, September, 1917.

The screw-worm (*Chrysomya macellaria* Fabricius) is a native of America, and is found from the extreme south to Canada, but is rarely abundant in the Northern States, as the fly is quickly killed in cold weather. The states of North America which suffer most severely are Texas, Oklahoma, New Mexico, Arizona and Southern California.

Practically all animals are attacked by this insect. Probably cattle suffer most ; hogs, horses, mules, sheep, goats and dogs follow in the order named. Wild deer (*Cariacus* sp.) and many of the smaller mammals are sometimes seriously infested. Human beings are also frequently attacked. The female lays its eggs in wounds or skin injuries, where the parasite remains throughout the larval stage. The pupa is usually found in the ground. A huge number of eggs may be deposited in a mass by a number of females. In livestock the parasite always causes loss of appetite and emaciation, and sometimes death. In some districts it makes calf-rearing almost impossible (the fly lays its eggs in the navel of the new-born calf, often causing its death) and older cattle have to be bought elsewhere. In sheep it causes emaciation and decreased milk production, and in all cases involves increased expenses for the watching and treatment of animals.

The screw-worm fly is the only species in the south-west of the United States which penetrates the sound tissues of animals, but other flies attack the diseased tissues of wounds and soiled wool. These flies are: — the black blowfly (*Phormia regina* Meigen), green bottle fly (*Lucilia sericata* Meigen), and gray flesh flies (*Sarcophaga texana* Aldrich, *S. tuberosa* var. *sarracenioides* Aldrich, *S. robusta* Aldrich). All these flies breed in decaying animal matter, especially in carcasses of large animals. If all dead animals were properly disposed of no cases of infection of living animals would occur.

The best method of control is the burning of carcasses. This reduces the danger of infection by anthrax, tuberculosis and similar diseases in the pastures and prevents the breeding of flies in the carcasses. If it is not possible to burn the carcasses they should be buried, covered with quicklime (especially if the death of the animal may be attributed to an infectious disease) and then covered with at least 2 feet of soil.

Methods of controlling the parasite in cattle are: — avoidance of injury, calving at a time when the flies are not abundant (between December 1 and the middle of April, and, in the north, from November 1 to June 1), destruction of ticks, performance of surgical operations (castration, dehorning, etc.) in winter or the beginning of spring, poisoning and trapping the flies. To prevent the larvae from infesting the wool of sheep, lamb early and dip and clip soiled sheep. To avoid dehorning, hornless types may be bred. The animals must be continually watched so as to discover the first symptoms of infection, and the larvae killed with chloroform, the wounds being then treated with pine tar to repel the flies.

Appended is a list of 33 publications issued by the United States Department of Agriculture on insects affecting the health of man and domestic animals.

305 — **The Cause and Prevention of Hairless Pigs, in the United States.** — WELCH, HOWARD, in *Montana Agricultural College Experiment Station, Circular 71*, pp. 37-47, 9 fig. Bozeman, Montana, 1917.

It has been known for some years that, in certain of the Northwestern States, the new-born of all the domestic animals were in some way defective. New-born pigs were hairless and seldom lived; the calves were often hairless and more frequently had goitre. The young of sheep and goats were similarly affected, while new-born foals, though neither hairless nor having goitre, were weak, seldom able to stand and usually died.

In Montana, the loss is probably heaviest in young pigs, for about 10 000 are estimated as dying from this cause annually. In some localities pigs are the only domestic animals affected, while in others, it may be lambs only. It is a disease of definite localities, occurring in Montana in the drainage basin of the Yellowstone, the lower Missouri, the Musselshell and some of the smaller tributaries; outside this zone, a number of scattered cases constitute about 5 % of the total loss. In some cases, the pig crop can be saved on moving the pregnant sows a mile or two out of the affected district during gestation. The malady varies curiously: one year it may cause 95 % loss, and nothing the year after. There are also variations in a sin-

gle pen of pregnant sows. Pigs born in March and April are more often affected than those born in May and June, while autumn-born pigs are frequently normal even in badly affected districts.

Amongst causes of the trouble have been suggested: — contagious abortion; alkali in the soil; some particular feed, such as alfalfa, flax, maize, or wheat; or some deficiency in the soil or water. All these causes have been studied by the author, but negative results were always obtained.

Post-mortem examinations showed: — that the hairless pig has a thick, pulpy skin, especially round the head, neck and shoulders; that the thyroid gland was very hypertrophied and the heart not fully developed. The development of goitre and the hairless condition are of related gravity. This led the author to suppose that goitre was the cause of the disease, and he found, by analogy with human goitre, that the hypertrophied thyroid glands contained much less iodine than the normal quantity, or even none. He therefore concluded that the cause of the malady is lack of iodine in the food and water given to the animals, and that it was worth testing whether this insufficiency could be compensated for by giving potassium iodide. Tests made with pigs (with 129.5 to 324 mgm. of potassium iodide per head per day), with female breeding stock during gestation, gave positive results. Iodide of potassium given to a pregnant female prevents goitre appearing in the newborn. Therefore, it is advisable to feed iodine to pregnant animals in regions where goitre is prevalent.

306 — **Iron as an Antidote to Cottonseed Meal Injury** (1). — WITHERS, W. A. and CARRUTH, FRANK, F., in *The Journal of Biological Chemistry*, Vol. XXXII, No. 2, pp. 245-257, 4 diagrams. Baltimore, November, 1917.

Experiments carried out at the Chemical Division of the North Carolina Agricultural Experiment Station, West Raleigh, showed that, though rabbits are very sensitive to poisoning by cottonseed meal (obtained by extraction of the oil by solvents) even when it has been cooked a long time, they could be successfully fed with this meal for a long period (the experiment lasted 106 days) if it were mixed with ferric ammonium citrate. The authors extended these experiments, using pigs as subjects, in order to investigate whether the harmful action of cotton seed meal is due to an injurious substance or, as some assert, to inadequate or badly proportioned diet.

Although the addition of iron salts is not to be recommended as a practical method for overcoming cottonseed meal poisoning, the experiments show that, when such salts are present, much larger quantities of the meal may be fed, with a resulting increase in body weight; in some cases it was even possible to prevent death, in many, to retard it. Further evidence of the presence of a toxic substance in the meal is the fact that extraction with alcoholic alkali removes the toxicity (experiments with rabbits). The authors assume the loss of toxicity to be due to: — 1) the formation of an insoluble iron salt of gossypol or one of its derivatives; 2) the catalytic

(1) See also *R.* January, 1918, No. 64. (*Ed.*)

acceleration of the oxidation of gossypol; 3) perhaps a tonic action of iron.

When cottonseed meal is treated with iron salts it turns brownish black, proving that a reaction takes place with some component of the meal. The action of iron salts on a solution of gossypol produces a similar colour. The fact that the effects of the toxic factor may be inhibited by the action of iron salts shows that the toxicity of cottonseed meal is not due to a lack of "vitamines" or to a deficiency in calcium, sodium and chlorine, as might be expected from the chemical analysis of a diet of maize and cottonseed meal.

It is interesting to note that, in the authors' experiments, wood ashes had no antidotal action in preventing the death of pigs fed on maize and cottonseed meal, but the animal receiving ashes made much better gains, probably because of the improvement in the inorganic part of the diet. The appended table gives the results of one of the four experiments. In each of the four experimental groups were 9 pigs fed with a mixture of 25 % cottonseed meal, and 75 % maize meal. To each 4 lbs. of feed the control group (to which no iron salts were given) received 1 gallon of water, group 2, 1 gallon of copperas solution (1 lb.  $\text{Fe SO}_4 \cdot 7\text{H}_2\text{O}$  dissolved in 50 gallons of water), group 3, 1 gallon of ferric chloride, containing approximately the same amount of iron as the preceding solution; group 4, 1 gallon of water with hardwood ashes *ad lib*. The experiment lasted 94 days.

*Effect of the addition of iron to a diet composed of 25 % cottonseed meal and 75 % maize meal.*

Group	Feed	Weight (in lbs.)				Deaths (among 9 animals)
		Initial	Final	Daily gain	Cottonseed meal eaten	
1	Control . . . . .	103.4	107	0.05	47	6
2	Copperas . . . . .	92.1	134.6	0.46	66	3
3	Ferric chloride . . . . .	102.2	163.2	0.68	80	1
4	Hardwood ashes . . . . .	98.3	137.7	0.67	50	7

307 - **The Poisonous Properties of the Two-Grooved Milk Vetch (*Astragalus bisulcatus*).** — BEATH, O. A. and LEHNERT, E. H., in the *University of Wyoming, Agricultural Experiment Station, Laramie, Wyoming, Bulletin No. 112*, pp. 58-67, 1 fig. Laramie, January, 1917.

As *Astragalus bisulcatus* is not mentioned as a poisonous plant, the above bulletin gives an account of it to warn stockmen of its poisonous nature. It grows in plains and valleys in the Rocky Mountain region. Milk vetch is possibly most dangerous when fully mature but, when dry (as hay), it seems more or less harmless. Experiments carried out at the Wyoming Agricultural Station have lead to the conclusions given below.

Milk vetch is certainly poisonous to cattle; its effect upon sheep is

uncertain ; 80 to 90 % of the animals affected die. Water easily removes the active poison from green or air-dried material. All parts of the plant contain poison, with a slight excess in the leaves. The poison is neither precipitated by basic acetate of lead nor decomposed at 100° C. ; it loses its toxicity on boiling with dilute acids, indicating its probable glucosidic character, as does the fact that a crystalline substance has been isolated giving reactions of glucosides ; at any rate, it is non-alkaloidal.

Thus far no chemical antidote has been found. When sufficient poison to cause death is introduced into the system, whether through the stomach or intravenously, it is quickly absorbed and soon produces symptoms of paralysis, by its action on the nervous system ; the action of the heart is also interfered with, and the poison no doubt kills by acting on this organ ; therefore drugs that stimulate the heart and the nervous system (alcohol, aromatic spirits of ammonia, belladonna extract, tincture of digitalis) should prove beneficial ; these remedies should be preceded by a drench of 1 to 2 lbs. of Epsom salts.

308 - **Experiments on the Reported Poisonousness of Wild Melon Fruit.** — DODD, SYDNEY, in *The Agricultural Gazette of New South Wales*, Vol. XXVIII, Pt. 2., pp. 815-819. Sydney, November 2, 1917.

Many Australian stock-owners believe the fruit of the wild or "paddy" melon (*Cucumis myriocarpus*) to be poisonous to livestock, causing injury to the nerves and blindness. The green part is also said to be harmful, but because it is indigestible rather than poisonous. In South Africa this fruit has been reported as poisonous to sheep and, in one case, as having caused the death of a child. Both in Australia and South Africa several feeding experiments have been made in which the wild melon was fed to animals, but contradictory and inconclusive results were obtained, because the fruit was eaten for a short time only, and as the disease it causes is chronic, it results only after it has been fed for a prolonged period. The ripeness of the fruit must also be taken into consideration, as some stock-owners assert that it is injurious only before it is ripe. In some districts the drovers gather the fruit to give to their horses.

The author carried out two series of experiments in which wild melon fruit was fed to three guinea-pigs, two rabbits, a sheep and a horse. Two of the guinea-pigs, fed on unripe fruit, died, the other guinea-pig and the rabbits, after eating the fruit for about a month remained healthy and normal. The sheep was forcibly fed with the fruit for 20 days without showing any sign of poisoning ; on the 21st. day it was asphyxiated through the carelessness of the attendant. The horse was fed for 51 days with wild melon mashed up with bran, in amounts of about 2 lbs. 2 oz. per day, then of about 4 1/4 lbs. per day. It showed no sign of disease.

It seems as if the ripe fruit of wild melon may be considered harmless, but the author does not consider his results conclusive and intends to continue the investigations.

309 — **Pyotherapy in the Treatment of Harness Wounds ; Some Considerations on the Efficacy and Absolute Non-Specificity of Anticryptococcal Pyotherapy on the Horse.** — VELU H., in the *Bulletin de la Société de Pathologie exotique*, I, Vol. X, No. 10, pp. 901-903. Paris, December, 1917. — II. Vol. XI, No 1, pp. 12-17. Paris, January, 1918.

I. — In the course of recherches on the pyotherapy of epizootic lymphangitis (1) the author has repeatedly found how efficacious is treatment with polyvalent vaccines (either anticryptococcal vaccine, or vaccine prepared from ordinary suppurations) for curing *non-specific* lesions, caused by harness.

During the negative phases, the peripheral inflammatory reaction becomes intense ; the separation furrow forms more quickly ; the necrosis tissue is eliminated more easily, on account of the increased suppuration ; surgical intervention becomes more easy, and the wound clears up without useless decay. During the positive phases, the wound cicatrises almost without suppuration, with surprising regularity and quickness. Local antiseptic treatment becomes almost accessory.

The author states that he has, by means of pyotherapy, rapidly cured arthritis and a severe traumatic synovitis, as well as obstinate bony fistulae. LIGNIÈRES (Bacteriotherapy in the treatment of Wounds, *Bulletin de la Société Centrale de Médecine Veterinaire*, 1915, pp. 544-548) has already pointed out that specific organisms are not the only ones that give good results when injected into sick subjects. An antianthrax vaccination may stay the spread in a herd of a disease in no way connected with anthrax ; wounds that wont heal may do so after injection of an organism unconnected with the disease, such as *B. coli*. On the other hand it is well known that the injection of any antigen is followed by a hyperleucocytosis.

In conclusion, pyovaccine provides a very efficacious, simple and economic method within the reach of all practitioners, for reducing, in considerable proportions, the time lost in laying-up for harness wounds.

II. — The polyvalent anticryptococcal pyovaccine prepared at the Casablanca Laboratory has been used for treating pyogenous lesions of the horse due to pathogenic agents other than the cryptococcus. The results clearly showed the definite action of the pyovaccine.

In every case, the injections brought about decreased local inflammation, less pain, the diminution, then disappearance, of suppuration, and in certain cases, sterilisation of the lesions. Their non-specific effect is undoubted, even when they do not bring about complete recovery.

The author quotes work of other experimenters on other vaccines, showing their non-specific action, and he concludes, speaking generally, that polyvalent, paraspecific pyotherapy is a very simple and economical method which, whether by results already obtained, or those rightly expected, should take a prominent place in the practice of veterinary therapeutics.

(1) See R., July 1917, No. 611 ; R., August 1917, No. 734 ; R., February 1918, No. 176 ; and No. 310 of this Review (Ed.)

310 — **The Curative Treatment of Epizootic Lymphangitis by Vaccinotherapy; Preparation of a Polyvalent Pyovaccine.** — I. VELU, H., in the *Recueil de Médecine Vétérinaire publié à l'Ecole d'Alfort*, Vol. XCII, No. 9 and 10, pp. 195–204. Paris, 1917. — II. IDEM, in the *Bulletin de la Société de Pathologie Exotique*, Vol. X, No. 8, pp. 681–684. Paris, 1917. — III. IDEM, in *Ibid*, Vol. XI, No. 1, pp. 10–11. Paris, 1918.

Work carried out at the Research Laboratory of the "Service de l'Élevage du Maroc" at Casablanca..

I. — The vaccine is obtained from pus from diseased horses and is, thus, an "anticyptococcal pyovaccine". The subcutaneous injection causes, more or less rapidly, a reaction of the organism shown by very clear clinical signs at the level of the specific lesions. First appears a *negative phase* (aggravation of all the symptoms), which is then replaced by a *positive phase*.

The question of treatment consists in finding out suitable doses, and the frequency of renewal, so as to cause insignificant negative phases and predomination of positive ones.

The author gives results obtained with sick horses, and describes the broad lines of his method, which has given excellent results.

II. — After new clinical observations on over 100 animals for over 6 months, the author, having slightly modified his method, gives the final technique as follows: —

1) Injections of pyovaccine cause a reaction with effects localised at the level of the lesions. There is a negative phase. Therefore, all lesions containing pus should be punctured from the start.

2) Subcutaneous injections of pyovaccine sometimes cause abscesses that heal slowly; for this reason, intravenous injections are advised, as giving quicker and more certain results.

3) The first 2 injections of pyovaccine, and especially the second, in strong doses (4 to 6 cc. for the first, 1.5 to 2.5 cc. for the second), produce intense and lasting positive phases. The doses should, in consequence, be strong and separated by intervals of 8, 10 or even 12 days. The giving of another injection should be delayed until the moment when the positive phase begins to slacken, that is, when the improvement begins to decrease, but one should not wait longer than this.

4) After the second injection the organism is very sensitive. So, after the third injection, small doses of pyovaccine (0.75 to 1.25 cc.) must be given. Fresh injections should be given immediately the positive phase begins to weaken, i. e., about every 5, 6, 7 or 8 days.

The author states that the effects of pyovaccination are not strictly specific, and that he has obtained, with anticyptococcal vaccine, excellent results in the treatment of obstinate fistulae or of considerable lesions that did not show the causal organism of epizootic lymphangitis.

III. — *Polyvalent* vaccines and serums are those that act against several species of organisms, and *polyethmic* vaccines and serums are those that act against several varieties of the same species. Under these conditions, pyovaccine prepared with products obtained from several horses suffering from epizootic lymphangitis, is a polyethmic anticyptococcal pyovaccine, for it solely contains cryptococci of different strains. In the open lesions of

the disease there are, besides the cryptococcus in abundance, numerous and abundant associations of bacteria that certainly play no unimportant part; a polyvalent pyovaccine can thus be prepared which will act both on cryptococci and associated organisms.

The technique for preparing the vaccine is as follows: Remove the pus from closed lesions by means of a sterilised syringe, after cutting the hair and disinfecting the skin over the abscess; also remove with the syringe the pus or serosity collected at the surface of open lesions, under the crusts covering them; read off the volume on the graduated syringe and empty into a sterilised flask containing a known quantity of ether and phenolated physiological serum at 5 ‰; mix well by shaking; mix together the pus obtained from several cases; add the quantities of ether and 5 ‰ phenolated physiological serum required to bring the vaccine to the ratio of 1 of pus to 1.5 of ether and 10 of phenolated physiological serum; filter through 4 to 6 sheets of sterile gauze.

The vaccine thus obtained will be a polyvalent antipyogenous vaccine for treating, not only epizootic lymphangitis, but also various pyogenous lesions of the horse.

311 - **Pyotherapy in Epizootic Lymphangitis; Researches in Italy.** — IANFRANCHI, A. and BARDELLI, P., in *Il Moderno Zoonatro*, Series V, Year VI, No. 12, pp. 261-275, diagrams 7. Bologna, December 31, 1917.

After summarising the work carried out by MANGAN, BELIN and VELU (1) on pyotherapy, the authors give a detailed description of their treatment of epizootic lymphangitis by means of pyotherapy, which has given completely negative results. "In all the animals treated, whether the lesions were slight, of moderate severity, or severe, the 2 series of 6 injections (each of 2 cc. of pyovaccine) with an interval of 8 days, caused no diminution of the progress of the disease"; even with subjects used as controls, during the experiment, it was found that the injections of pyovaccine "have accelerated and aggravated the disease". Therefore, according to the authors, at the present state of our knowledge, autotherapy and pyotherapy are not methods of treatment the use of which could be advised in epizootic lymphangitis.

312 - **The Vitality of the Rinderpest Virus Outside the Animal Body under Natural Conditions.** — SHILSTON, A. W., in the *Memoirs of the Department of Agriculture in India*, Veterinary Series, Vol. III, No 1, pp. 32 + IV plates. Calcutta, October, 1917.

Great uncertainty has existed in regard to the length of time that rinderpest can exist outside the animal body, either under natural conditions or when special measures are taken to preserve its vitality. On this account, the experiments described in the present Memoir, were designed to ascertain the duration of the vitality of the rinderpest virus 1) on ground in the open air, 2) in closed sheds, 3) in faeces, urine and mucous discharges, and 4) in meat, blood and bones under varying natural conditions. To make the

(1) See also R., 1917, No 734; R., February 1918, No 177 and 178. (Ed.)

covering a distance of 3.9 to 4.8 km. per hour, did this work with an expenditure of energy equal to 0.580 kilogrammeter (to move 1 kgm. 1 meter). Although the weight of the dog varied 17 % during the experiments, and the speed of the treadmill 20 %, the maximum difference in energy expended was 1.7 %. (It will be seen that there is a relation between the weight of the animal and the energy required to move its body horizontally; a 15 % gain in weight caused a corresponding gain of 15 % in the energy requirement).

\* Dog resting.

INFLUENCE OF MECHANICAL WORK DURING THE HOURS IMMEDIATELY FOLLOWING THE INGESTION OF GLUCOSE. — The same dog after the ingestion of 70 or 100 gm. of glucose in water did the same amount of work with an energy expenditure of 0.550 kilogrammeters (see Table I B.) Thus, to supply the same amount of mechanical work, the dog, immediately after the ingestion of glucose, requires about the same amount of energy (slightly

less) than when it does the work 18 hours after ingestion of the standard diet. It may, however, be said that, in spite of the addition to the weight of the dog of the aqueous solution ingested which increased the total weight to be displaced, the expenditure of energy was only 0.550 kilogrammeters; this figure, compared with the preceding one (0.580 kilogrammeters), shows that the ingestion of carbohydrates diminishes the energy required for a given piece of work by 5 %.

**INFLUENCE OF MECHANICAL WORK 4 OR 5 HOURS AFTER THE INGESTION OF MEAT.** — The results obtained after the ingestion of meat (see Table I C.) are in perfect agreement with those found by RUBNER in his experiments on man referred to above. The dog, 4 or 5 hours after the ingestion of meat, accomplished the work with an expenditure of energy exceeding the basal metabolism; this energy results from the sum of the specific dynamic action (1) of meat + the energy necessary for the work, the total being equal to an average of 0.587 kilogrammeters.

The ingestion of alanine (20 gm.) gives similar results, *i. e.* an energy expenditure resulting from the specific dynamic action of the substance and the work supplied.

TABLE II. — *Influence of mechanical work upon metabolism in fasting.*

Date '(1917)	Experi- ment No.	Weight (kg.)	Days of fast	Indirect calori- metry (cal.)	Respi- ratory quotient	Work in meters trav- elled	Calories above the basal per 1000 meters travelled	Kilogram- meters required
March 29 . . . . .	28	8.75	3	73.7	0.71	4 796	12.06	0.584
» 30 . . . . .	29	8.6	4	16.0	0.74	—	—	—
» 31 . . . . .	30	8.55	5	70.2	0.724	4 719	11.5	0.570
April 2 . . . . .	31	8.35	7	15.0	0.74	—	—	—
» 3 . . . . .	32	8.1	8	14.3	0.715	—	—	—
			8	70.8	0.719	*5 023	11.2	0.587
» 5 . . . . .	33	8.2	9	14.4	0.73	—	—	—
» 9 . . . . .	34	7.6	13	12.4	0.75	—	—	—
»	—	—	13	62.7	0.717	*4 710	10.6	* 0.595

\* Average = 0.584 kilogrammeters.

**INFLUENCE OF MECHANICAL WORK DURING FASTING.** — The dog having lost about 20 % of its weight after 13 days' fasting, performed the same mechanical work with an average expenditure of energy of 0.584 kilogram-

(1) Term used by RUBNER to express the loss of energy peculiar to certain foodstuffs caused by the changes they undergo in the organism. (See B. 1914, p. 435, ZUNTZ, N. *Experiments and Points of View in the Study of Animal Metabolism with the Aid of the Respiratory Apparatus.* (Ed.)

meters (see Table II). If the results obtained during fasting are compared with those obtained when the animal is in the best nutritive condition (see Table I) it is seen that, to accomplish the same amount of work, the same expenditure of energy is required in both cases, in spite of the fact that, in the first, the dog has lost 20 % of its weight.

CONCLUSION. — To move 1 kilogram of body substance 1 meter through space the animal requires a *constant* expenditure of energy (0.580 kilogram-meter on the average), *independent* of its weight and of the specific dynamic action of the foods ingested. Only an abundant supply of glucose reduces slightly this expenditure.

#### FEEDS AND FEEDING

- 315 - **The Effect of High Temperature on the Nutritive Value of Foods.** — HOGAN, ALBERT G., in *The Journal of Biological Chemistry*, Vol. XXX, No. 1, pp. 115-123 + 9 diagrams. Baltimore, May, 1917.

The experiments described were made on rats in the Department of Chemistry of the Kansas Agricultural Experiment Station, Manhattan.

In a previous paper (*Journal of Biological Chemistry*, Vol. XXVII, p. 193, 1916) the author showed that young rats are unable to grow on a diet that has been subjected to high temperatures. Many investigators believe the so-called accessories to be destroyed by exposure to heat. In order to verify this hypothesis the author undertook new experiments, using as food maize and a mixture of maize and white of egg, one or both of which had been heated in the autoclave for 6 hours under a 30 lbs. pressure. It was found that heat had little or no effect on the white of egg, but that each time the maize was heated the diet became inadequate in some respect. To ascertain whether the protein had been changed, a relatively pure protein — white of egg — was heated in the autoclave for 6 hours at a 30 lbs. pressure. This protein was carefully dried and mixed with protein-free milk, butter, starch and agar in such proportions that the protein formed about 9 % of the ration. In further experiments, for the white of egg was substituted unheated casein (control) and casein heated in the autoclave for 2 hours under a pressure varying from 15 to 45 lbs. It was seen that the action of heat caused no essential modification of the food value of either the white of egg or the casein.

The author concludes that heating such as carried out in his experiments does not materially decrease the food value of proteins. The hypothesis that one or more of the so-called food accessories may be injured by high temperatures seems justified.

- 316 - **The Supplementary Dietary Relationship between Leaf and Seed as Contrasted with Combinations of Seed with Seed.** — MCCOLLUM, E. V., SIMMONDS, N. and PITZ, W., in *The Journal of Biological Chemistry*, Vol. XXX, No. 1, pp. 13-32 + 14 diagrams. Baltimore, May, 1917.

At the Agricultural Station of Wisconsin, Madison, the authors had previously carried out a series of preliminary feeding experiments with a number of natural foods of one variety completed by the addition of one or more isolated and chemically pure dietary factors (protein, mixture of

inorganic salts, fat-soluble A, water-soluble B\*). In this way they studied wheat (1) maize (2), rice (3), oat kernels (4) and white beans (5).

With the exception of polished rice and beans these seeds resemble each other closely in their dietary properties: — a) the proteins are of relatively, poor quality furnishing certain essential amino-acids in amounts below the optimum.; b) the content and composition of the inorganic portion of each seed are of a character which cannot induce normal growth and must be corrected by certain salt additions; c) the content of the fat-soluble A is inadequate to supply the needs of a growing animal over a prolonged period. Unpolished rice closely resembles the other seeds mentioned above, but polished rice, which has lost both its bran layer and its germ, is deficient, not only in the above-mentioned factors, but also in water-soluble B. The common bean differs from the other seeds particularly in the poor quality of its proteins. These contain but little of one or more of the essential amino-acids, so that beans should always be combined with other natural foods capable of supplying the proteins which supplement this deficiency.

In the paper under review the authors give data obtained recently which clearly show the general lines along which successful nutrition may be obtained when the diet is purely vegetarian. Their experiments, which have lasted over 10 years, carried out with rats and pigs, convinced them that these two species have essentially the same food requirements. Neither species can grow satisfactorily when restricted to one of the cereal grains; as regards growth and reproduction both respond in the same way to specific modifications of a diet thus restricted. In the experiments described, made with rats, it was found impossible to make up a ration derived solely from the seeds of plants capable of giving normal nutrition during the growing period, even though two to five seeds of widely different varieties were employed. When the animals were put on a simple and unvaried diet of a mixture of leaves (alfalfa) and seeds, very different results were obtained.

It was impossible to secure appreciable growth with the following mixtures of seeds with salt-free water.

- 1) maize 90, flaxseed oil meal 10;
- 2) wheat 20, maize 20, rolled oats 20, hemp seed 20, millet seed 20;

(Ed.)

3) wheat 25, maize 25, rolled oats 25, hemp seed 25 ;

4) wheat 33, maize 33, rolled oats 33.

These rations represent two distinct types ; rations 1 and 2 promote good growth if suitable inorganic salts are added, but not otherwise ; ration 3, after a period of suspended growth, responds less well to the addition of salts in its effects than the two preceding rations ; ration 4 does not support growth. This shows that rations 1 and 2 contain a sufficient quantity of the factors fat-soluble A and water-soluble B, as well as proteins of adequate quality and enough assimilable energy as carbohydrate and fat. The preceding experiments (described above) showed that maize, wheat and oats contained an insufficient amount of the fat-soluble A, and it is, therefore, evident that flaxseed meal and millet seed contain a much greater

amount of this dietary factor. This is confirmed by the results obtained with ration 3 which contains neither flaxseed meal nor millet seed. Ration 4 is deficient, not only in the fat-soluble A, but also in salts.

*It is difficult, if not impossible, to obtain even moderate growth over an extended period on a diet restricted to the seeds of plants.* Since the water-soluble B is abundant in all the seeds, and the fat-soluble A present in large quantities in some of them, the failure of the seeds to promote growth must be attributed to the composition of their inorganic fraction. Of the seven seeds most important for human nutrition and animal production (rice, maize, wheat, oats, beans, cotton, flax) only cottonseed and flaxseed have a high inorganic content, and in all of them, as with seeds in general, the ash is very poor in sodium, calcium and chlorine.

The following data are taken from the paper by E. B. FORBES, *Ohio Agricultural Experiment Station Bulletin* 207, 1909.

The leaf and seed rations used to ascertain how far leaves can supplement the deficiencies of the seeds were : —

- 5) rolled oats 50, alfalfa 50 ;
- 6) rolled oats 60, alfalfa 40 ;
- 7) rolled oats 70, alfalfa 30 ;
- 8) wheat 60, alfalfa 40 ;
- 9) wheat 70, alfalfa 30 ;
- 10) maize 60, alfalfa 40 ;
- 11) maize 70, alfalfa 30 ;
- 12) maize 80, alfalfa 20 ;
- 13) maize 90, alfalfa 10 ;
- 14) peas 60, alfalfa 40.

The results obtained led to the following conclusions : —

*The leaf is distinctly different from the seed in its dietary properties in two respects: — its total inorganic content is very high, and it is especially rich in both sodium and calcium, both of which are deficient in the seeds generally.* In addition the leaf is several times richer in fat-soluble A than are wheat, oat and maize kernels. Certain seeds contain this substance to nearly the same extent as the leaf; hemp seed is distinctly superior in this respect to the seeds just mentioned, and flaxseed and millet seed are still richer than hemp seed. The fat-soluble A content is highest in the smallest seeds, probably because of the relatively large proportion of germ contained in them.

317 - **Indian Cattle Census.** — *The Agricultural Journal of India*, Vol. XII, Part. IV, p. 676. Pusa, October, 1917.

The following figures, recently published by the Director of Statistics of India are based on cattle censuses which are taken annually in some provinces and quinquennially in others. It is stated that a general census for all provinces will be taken during the year 1919-1920.

The total number of cattle in British India is 147 336 000. Of this, bulls and bullocks account for 48 664 710, cows for 37 481 273, buffaloes for 19 025 079, and young stock for 42 184 790. The following are the provincial figures: —

STOCK RAISING:  
ORGANISATION  
AND  
ENCOURAGE-  
MENT

United Provinces	31 741 000	22 % of total	Burma . . . . .	5 882 000	} 0 % of total
Bengal. . . . .	25 324 000	17 %	Assam . . . . .	3 576 000	
Madras . . . . .	21 761 000	15 %	NorthWest Frontier Province. .	1 271 000	
Bihar and Orissa	20 119 000	14 %	Ajmer-Merwara . . . . .	351 000	
Punjab . . . . .	15 489 000	11 %	Dehli. . . . .	148 000	
Central Provinces and Berar	11 857 000	8 %	Coorg . . . . .	131 000	
Bombay and Sind	9 677 000	7 %	Manpur. . . . .	6 000	

The number of cattle per 100 acres of cropped area ranges between 32 in Bombay and Sind and 100 in Bengal, while the number per 100 of population ranges between 36 in Dehli and 95 in the Manpur Pargana. The average for British India as a whole is 65 per 100 acres of cropped area and 61 per 100 of population.

The number of sheep is given at 23 015 836, of which Madras possesses 10 765 543 and the Punjab 4 676 899. The number of goats was 33 338 487, horses and ponies, 1 653 379, and mules and donkeys, 1 512 205.

The statistics relating to sheep, goats, horses, and ponies, and mules and donkeys, exclude Bengal, from which no returns regarding these animals are at present received.

318 - **Herd Books of the Argentine Rural Society** (r). — DE ANCHORENA J., in the *Anales de la Sociedad Rural Argentina*, Year I, II, Vol. L, L, pp. 642-644. Buenos Ayres, October 1917.

The appended tables give a summary of the entries in the herd books of the Argentine Rural Society for the last year (October 1, 1916-September 1917) and since their foundation. All pure breeds of cattle, horses, asses, sheep and pigs, whether produced in or imported into the Argentine, are included.

319 — The Stud Beef Cattle Breeders' Association of Australia. — *The Pastoral Review*. Vol. XXVII, No. 10, p. 933. Melbourne, October 16, 1917.

The movement initiated in Sydney about three months ago in the direction of forming a stud beef cattle breeders' association received official endorsement when the members of the *Stud Beef Cattle Breeders' Association of Australia* met in general meeting to consider and adopt the rules and regulations drawn up by the provisional council.

The future value of the organisation in fostering pure cattle breeding was generally recognized, as well as the fact that the opportunities of doing

valuable work in this direction in Australia are boundless. The men who have been elected to manage this new Association are well-known and successful breeders from the various States of the Commonwealth and are fully competent to make it an unqualified success.

320 — **On the Use of Certain Marine Algae for Feeding Horses.** — ADRIAN, in *Comptes rendus des Séances de l'Académie des Sciences*, Vol. CLXVI, No. 1, pp. 54-56. Paris, January 7, 1918.

HORSES

The author, having been offered a product obtained from *Laminarias* to be used for waterproofing cloths, noticed that the composition of the treated seaweed resembled that of oats, as is shown by the appended figures: —

	Laminarias treated	Oats
Water . . . . .	14.40 %	12.55 %
Carbohydrates . . . . .	52.90	66.80
Nitrogenous matter . . . . .	17.30	9.10
Cellulose . . . . .	11.50	8.45
Ash. . . . .	3.90	3.10

The author tried the product on 2 lots of 3 horses suffering from lymphangitis; one lot, used as control, was given the ordinary feed of oats, hay, straw, while for the second the seaweed replaced the oats.

After 24 days, it was found that the horses fed on seaweed had increased in weight by 6 %, while their general condition was much improved, and the lymphangitis had disappeared, though still persisting in the first lot. This action on the disease, if it is confirmed, might possibly be due (according to MM. LAPICQUE and LEGENDRE of the Museum, who were consulted on this question) to the traces of organic iodine in the algae.

One certain result was obtained: — horses had eaten, digested and assimilated the new food replacing oats.

A further experiment was tried with 2 lots of 20 cavalry horses; the first lot were fed normally, while the second received 1 kg. of alimentary seaweed replacing 1 kg. of oats.

The experiment, which lasted 2 months, confirmed the previous one; the horses fed on the seaweed had put on 13 kg. by the end of the trial, while the control horses had barely gained 2 kg.

The author considers 0.750 kg. of alimentary seaweed to be equivalent to 1 kg. of oats.

The experiment is all the more interesting since *Laminarias* are abundant on the coast of Brittany. The author discusses their use in human nutrition, as regards which very interesting results have been obtained.

321 — **Relation between the Weight of the Carcass and that of the Meat in Beef Cattle.** — DECHAMBRE, in *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. IV, No. 1, pp. 25-28. Paris, January 9, 1918.

CATTLE

The meat obtained from an animal is equal to the difference between the net weight and the total weight of the bones, suet, etc. The most

important of these factors is the carcass, a knowledge of which would form a sound basis for the selection of slaughter breeds.

The relation between the weight of the carcass and that of the meat is influenced by many factors, such as age, sex, breed, maturity, and, above all, the condition of the animal produced by the degree of fattening. The author's experiments to determine this relation were carried out with a large number of animals, representing a total weight of meat of 51 031 lbs. in quarters containing 9 788 lbs. of bone. The average ratio of bone to meat is, therefore, 19.18 %. The extent of fattening greatly influences this ratio. It is usually expressed by the yield per cent. in meat, which is the ratio between live weight and the weight of the quarters. In the meat studied the extent of fattening is dependent on the amount of suet removed for preserving. The author, therefore, determined this amount and calculated its ratio to the weight of the quarters. When this ratio is compared with that between the bone and meat, it is seen that the figures vary inversely: — the fatter the animal the lower the proportion of bone.

The author's conclusions are: — 1) in medium fat and fat cattle, which generally give a net yield of meat varying between 55 and 58 %, the ratio between bone and meat is between 16 and 18 %; 2) in animals in good condition, yielding 50 to 52 %, the ratio is, on an average, 20 %; 3) in animals yielding less than 50 % (47 to 49 %), the ratio rises to 22 %, or a little more (22.63 %), though still below the 25 % generally admitted in the meat trade.

**322 - A Statistical Study of Body Weights; Gains and Measurements of Steers During the Fattening Period.** — SEVERSON, B. O. and GERLANGH, P., in the *Journal of Agricultural Research*, Vol. XI, No. 8, pp. 383-394 + Plates 38-39. Washington, D.C., Nov., 1917

During the winter months of 1914-1915, 1915-1916 and 1916-1917, a series of body measurements of steers were made at the Pennsylvania Experiment Station, at the beginning and close of feeding experiments, for three consecutive years, with the purpose of determining the average body measurements of 2-year-old steers at the beginning and close of the fattening period and the relationship of other definite body measurements to each other, and to note those measurements that could be used in selection as a means of reducing the experimental error in feeding experiments and a study of variation in the measurements themselves. Another object was to find out the correlation of gains to initial body measurements and to changes in body dimensions.

All measurements taken on a total of 216 animals divided into seven lots each year are indicated in Table I. These steers were relatively uniform as feeders, varying in market grades from "fair" to "choice", the majority being "good" feeders; 92 were Hereford grades, 84 Shorthorn grades, 18 Aberdeen Angus grades, 7 Shorthorn × Hereford crosses, 3 Shorthorn × Aberdeen-Angus crosses, and 3 Hereford × Aberdeen-Angus crosses. In no case did a steer fail to show some infusion of improved beef blood. The average initial weight of the 216 steers was 900.112 pounds with 700 and 1300 pounds as extremes. The steers

were as uniform in quality, weight, and condition as would ordinarily be obtained for feeding purposes. Each year 60 steers were divided into five lots of 12 each selected with as much care for uniformity of weight, breeding, condition and quality as possible. The feeding of these various lots was done with rations affording very nearly the same opportunity for gains in live weight and condition of flesh for marketing.

Table I includes all records for the three years, while the correlation tables include the data during the first two years. All body measurements except circumferences were made with the steel caliper; all circumferences were measured with a steel tape graduated in inches. The probability of error in measurements is a factor not considered, thus necessitating a larger number of measurements to reduce the probable error.

TABLE I. — *Average initial and final measurements of 2-year-old steers fattened for market during a 140-day feeding period.*

Measurement	Initial measurement.		Final measurement.		Difference in measurements	Percentage increase
	Number of steers	Average	Number of steers	Average		
		Pounds		Pounds	Pounds	
Weight . . . . .	216	900 112	216	1,188.398	288 286	32.02
		Inches		Inches	Inches	
Width of head . . . . .	214	8.832	216	9.112	0.280	3.16
Length of head . . . . .	214	19.411	216	19.892	0.481	2.48
Length of neck . . . . .	103	19.163	72	20.990	1.827	9.53
Width of shoulders . . . . .	214	16.412	215	18.459	2.047	12.42
Width of front flank . . . . .	214	16.378	216	18.358	1.980	12.08
Width of paunch . . . . .	214	23.612	216	26.101	2.489	10.54
Width of rear flank . . . . .	154	19.527	216	22.744	3.217	16.42

Chest to ground . . . . .	214	22.876	216	24.013	0.237	1.03
Hind flank to ground . . . . .	214	29.128	216	30.202	1.074	3.68
Hock to ground . . . . .	142	20.795	204	20.914	0.119	0.57
Withers to ground . . . . .	214	49.224	216	53.870	4.646	9.43
Hips to ground . . . . .	202	50.855	214	52.411	1.556	3.05
Shonlder to buttock . . . . .	214	53.763	216	57.988	4.225	1.85
Circumference of chest . . . . .	214	73.014	216	77.694	4.680	6.40
Circumference of paunch . . . . .	214	80.256	216	88.301	8.045	10.02
Circumference of hind flank . . . . .	214	71.364	216	78.685	7.321	10.25
Circumference of muzzle . . . . .	141	17.198	143	17.930	0.832	4.83

These 216 steers gained at the rate of 2.058 pounds daily for 140 days.

The following average initial measurements show a marked similarity: the length of head, length of neck, and width of rear flank, which

vary from 19.163 to 19.527 inches; the width of shoulder and front flank differ by only 0.034 inch; the hips and thurls (hip joint) in width are 17.682 inches and 17.204 inches, respectively; and circumference of the body in the region of the chest and hind flank are 73.014 and 71.364 inches respectively. The height at the withers of a "feeder" steer is 1.631 less than the height at the hips. The length of body from shoulder point to buttock is only 2.908 inches greater than the greatest height at the hips.

The average measurements at the conclusion of the fattening period show similarity as follows: The length of head, width of hips, and distance of buttock from hips varying within 0.638 inch of each other; the width of shoulder, front flank, and thurls are almost identical; and the circumference of the chest and hind flank are more alike than their initial measurements.

The height has increased more at the withers than at the hips; thus a 2-year-old steer changes his greatest height from the hips to the withers while receiving market conditions. In circumference the increase was greater for the hind flank than for the chest; thus the greater circumference of the chest at the initial measurement becomes less than the circumference of the hind flank in the finished steer. In fattening, the greatest width at paunch and the greatest depth of body at the chest become more nearly alike, as shown by a difference of 3.118 inches at the initial measurement and 1.688 inches at the concluding measurement.

In all cases the difference between the initial measurement and the final measurement shows an increase in dimensions due to depositions of fat, muscular development and growth. The regions of the body covered by the greatest amount of muscular development show greater increased dimensions than those having less muscular covering.

In the regions where the growth would show the greater relative influence the least changes take place as shown in the width of head, length of head, distance from chest to ground and hock to ground. The greatest increase in width took place in the hind flank rather than in the paunch, where it would seem natural to have the greatest increase because of feed capacity and condition. The thick layer of flesh and fat deposits in the region of the hind flank, together with the distension of this region of the body in a fattened steer, are responsible for the greater width in this part of the body. The width of loin, hips, thurls, shoulders, and front flank shows changes in dimensions caused mainly by increased condition of flesh.

The increase in height at the withers of 4.646 inches is not all due to growth alone, a larger portion of this increase being caused by the flesh covering over the withers and the deposition of fat in the muscular tissues of the shoulder region. The fat deposit and muscular development causes the shoulder blade to be held more rigidly; thus, the body in the chest region rises between the shoulder blades, as indicated by the greater distance between the withers and the upper border of the shoulder blade. The greatest change in the body measurements was the circumference of the paunch. This, however, was proportionately less than the increase of 7.321 inches in circumference of the hind flank. The fact that the distance of chest to

ground and hind flank to ground did not show greater difference was due to lowering of the flank by deposition of fat in that region and the fat covering over the region of the chest. The region of the body possessing the most valuable eatable parts on the whole are affected most in the fattening process.

**CORRELATION TABLES.** The following table is here presented as illustration of the methods used in obtaining the facts presented in tables III and IV.

TABLE II. — *Correlation of average daily gain of steers during a feeding period of 120 to 140 days and the weight at the beginning of a feeding period.*

Daily gain (pounds)	Initial weight per steer (pounds)													Total
	1 300	1 250	1 200	1 150	1 100	1 050	1 000	950	900	850	800	750	700

Correlation. . . . . do. 0.0364 ± .036														

The results shown in table III are based on data collected on steers during the two winter periods of 1914-15 and 1915-16. All measurements considered in this table are initial measurements, except those that show increases of dimensions at the close of the fattening period as compared with the initial measurements. The coefficient of variation is shown to be greatest on increases in circumference of hind flank, paunch, and chest, and the increase in gains in live weight.

These measurements all relate to increased dimensions and occur in those parts of the body that show relatively high percentage increase over initial body measurements (Table I).

Of the initial measurements the greatest coefficient of variation is 11.9 ± 0.04 per cent for initial live weight. In all the chest measurements the coefficients of variation are relatively high: Width at point of shoulder

9.3  $\pm$  0.52, width of fore flank 10.4  $\pm$  0.6, depth of chest 6.1  $\pm$  0.34, and circumference of chest 6.9  $\pm$  0.39. Likewise the mid and posterior regions of the body show variations, the rear flank with a coefficient of variation of 8.7  $\pm$  0.48, circumference of rear flank 6  $\pm$  0.34, width of loin 7.5  $\pm$  0.43, width of thurls 5.9  $\pm$  0.34, circumference of paunch 11  $\pm$  0.62 and distance of hips to buttock 5.2  $\pm$  0.29.

The measurements affected most by growth show the least variations and include the distance of shoulder point, rear flank, and withers from the ground, length of head, and distance of shoulder point to buttock.

In general Table III shows the greatest variation in those regions of the body which change most in a fattening steer and those regions affected most by deposition of fat and development of muscular tissue.

TABLE III. — *Means, standard deviations, and coefficients of variation presented in correlation tables.*

Number of steers	Measurements	Mean	Standard deviations	Coefficient of variation
		pounds	pounds	Per cent
388	Average daily gain . . .	1.93 $\pm$ 0.016	0.446 $\pm$ 0.011	23.1 $\pm$ 0.84
388	Initial live weight . . .	893.93 $\pm$ 3.94	106.88 $\pm$ 2.77	11.9 $\pm$ .04
142	Total gain in live weight	288.55 $\pm$ 3.10	54.77 $\pm$ 2.19	19.1 $\pm$ 1.08
		Inches	Inches	
142	Increase in circumference of chest . . . . .	8.13 $\pm$ .10	1.87 $\pm$ .074	23.0 $\pm$ 1.30
142	Width of rear flank. . .	19.25 $\pm$ .09	1.69 $\pm$ .06	8.7 $\pm$ .48
142	Circumference of rear flank	72.76 $\pm$ .25	4.40 $\pm$ .17	6.0 $\pm$ .34
142	Height of shoulder point	34.10 $\pm$ .08	1.57 $\pm$ .06	4.5 $\pm$ .25
142	Height of rear flank . .	30.23 $\pm$ .09	1.67 $\pm$ .06	5.5 $\pm$ .31
142	Distance, hip to buttock	18.69 $\pm$ .05	.99 $\pm$ .03	5.2 $\pm$ .29
137	Width of loin . . . . .	13.96 $\pm$ .06	1.05 $\pm$ .22	7.5 $\pm$ .43
142	Circumference of chest .	69.82 $\pm$ .22	3.91 $\pm$ .01	6.9 $\pm$ .39
142	Depth of chest . . . . .	25.77 $\pm$ .08	1.59 $\pm$ .063	6.1 $\pm$ .34
142	Width of fore flank. . .	15.02 $\pm$ .08	1.57 $\pm$ .06	10.4 $\pm$ .60
142	Distance, chest to ground	22.89 $\pm$ .06	1.18 $\pm$ .04	5.1 $\pm$ .28
136	Width of thurl. . . . .	17.36 $\pm$ .05	1.03 $\pm$ .04	5.9 $\pm$ .34
142	Length of head. . . . .	19.53 $\pm$ .04	.81 $\pm$ .03	4.1 $\pm$ .23
142	Length of shoulder to buttock . . . . .	55.66 $\pm$ .17	3.02 $\pm$ 2.84	5.4 $\pm$ .30
142	Increase in circumference of paunch . . . . .	8.26 $\pm$ .16	2.96 $\pm$ .11	35.8 $\pm$ 2.02
142	Height of withers. . . .	49.50 $\pm$ 1.07	1.95 $\pm$ .07	4.9 $\pm$ .27
142	Width at point of shoulder	16.42 $\pm$ .08	1.54 $\pm$ .06	9.3 $\pm$ .52
142	Circumference of paunch.	81.60 $\pm$ .56	10.04 $\pm$ 4.02	10.0 $\pm$ .62
138	Increase in circumference of rear flank . . . . .	7.52 $\pm$ .20	3.51 $\pm$ .14	46.6 $\pm$ 2.67

Table IV, a summary of the coefficients of correlation, shows that increases in body measurements have a closer relationship with gains in live weight than the initial measurements. With the exception of initial weight

these measurements, as shown in Table II, also had high coefficients of variation.

The correlation coefficients for the two body circumferences of chest and rear flank, the width of thurls (hip joint), and the distance of hip to buttock show the closest relationship of all the initial measurements with gains in live weight. This suggests the possibilities of using these measurements in the selection of feeding steers, at least for experimental purposes, as a means of reducing the experimental error caused by individuality of animals.

The measurement of initial weight shows no relationship with gains, although this is usually considered one of the most important factors in selection of steers for experimental purposes.

Measurements that show intermediate relationship as indicated by coefficients of correlation are width of loin, depth of chest, width of fore flank, length of head, height of withers, circumference of paunch and width at shoulders.

TABLE IV. — *Summary of correlations.*

Correlating	Correlation coefficient	Correlating	Correlation coefficient
Gain with initial live weight	$0.036 \pm 0.036$	Gain with initial length of head	$0.182 \pm 0.037$
Gain with increase in circumference of chest . . . . .	$.460 \pm .044$	Gain with initial length from point of shoulder to buttock	$.020 \pm .056$
Gain with initial width of rear flank . . . . .	$.079 \pm .083$	Gain with increase in circumference of paunch . . . . .	$.306 \pm .036$
Gain with initial circumference of rear flank . . . . .	$.221 \pm .053$	Gain with initial height of withers . . . . .	$.163 \pm .054$
Gain with initial height of point of shoulder . . . . .	$.061 \pm .056$	Gain with initial width of shoulders . . . . .	$.144 \pm .055$
Gain with initial height of rear flank . . . . .	$.053 \pm .055$	Gain with initial circumference of paunch . . . . .	$.124 \pm .055$
Gain with initial length of hip to buttock . . . . .	$.271 \pm .053$	Gain with increase in circumference of rear flank . . . . .	$.203 \pm .055$
Gain with initial width of loin	$.108 \pm .085$	Width of thurls with height of rear flank . . . . .	$.380 \pm .049$
Gain with initial circumference of chest . . . . .	$.238 \pm .053$	Circumference of chest with height of withers . . . . .	$.621 \pm .034$
Gain with initial depth of chest	$.130 \pm .046$	Width of loin with height of chest from ground . . . . .	$.179 \pm .057$
Gain with initial width of fore flank . . . . .	$.164 \pm .054$	Width of chest with depth of chest . . . . .	$.365 \pm .072$
Gain with initial distance of chest to ground . . . . .	$.077 \pm .056$		
Gain with initial width of thurls . . . . .	$.224 \pm .054$		

Measurements in which slight or no relationship exist as shown by correlation coefficients are initial live weight, width of rear flank, height at shoulder point and the distance of rear flank and chest from the ground.

A close relationship of circumference of chest with height of withers

is indicated by  $r = 0.621 \pm 0.034$ . Likewise, the width of chest and depth of chest by  $r = 0.365 \pm 0.072$  show a definite relationship.

The hind quarters of a steer are more important than the fore quarters in determining the gaining capacity of a steer, with the exception of the circumference of chest as shown by a correlation coefficient of  $0.224 \pm 0.054$  for width of thurls,  $0.271 \pm 0.053$  for distance of hip to buttock and  $0.221 \pm 0.053$  for circumference of rear flank.

The following points (see p. 361), held by authoritative judges of live stock to be important, are not substantiated by the results of this study thus far: Initial weight of steers, closeness to the ground of chest and hind flank, and the length of body from shoulder to buttock. The circumference of chest and rear flank are more important in ascertaining gains than feed capacity as indicated by the circumference of paunch.

### 323 - Influence of the Degree of Fatness of Cattle upon their Utilization of Feed. —

ARMSBY, H. PRONTISS and FRIES J. AUGUST, in the *Journal of Agricultural Research*, Vol. XI, No. 10, pp. 451-472, Tables, 1 fig., bibliography of 8 publications. Washington, December 3, 1917.

It is well known that the gain in live weight per unit of feed diminishes as fattening progresses; it is supposed that the cells of the adipose tissues, as they become loaded with fat offer an increasing resistance to the deposition of added fat, to overcome which increased expenditure of energy is required. Consequently a given amount of food gives a smaller gain in fat in a fat animal than in a thin one as a result of a corresponding increase in heat production and a reduction in the net energy value of the feed. Mr. ARMSBY, Director of the Institute of Animal Nutrition of the Pennsylvania State College, and the Assistant Director, Mr. FRIES, have investigated this subject by a direct comparison of the metabolism of an animal in ordinary condition and when well fattened.

#### *Rations and periods.*

Period	Preliminary period	Digestion period	Daily ration	
			Hay	Concentrates
			kg	kg
Period 1	November 2-12	November 13-22	1.7	3.4
Transition	(December 23-29)	—	—	—
Period 2	November 30-Dec. 10	December 11-20	3.5	7.0
Fattening	(Dec. 22-March 14)	—	—	—
Period 3	March 15-25	March 12-April 4	3.8	7.6
Period 4	April 5-15	April 16-25	2.0	4.0

METHOD. — *Subject*: a pure-bred shorthorn steer about 2 years and 9 months old at the beginning of the experiment. — *Rations and periods*: the animal received a basal ration of alfalfa hay and a mixture of concentrates (1 part of cottonseed meal, 2 parts of wheat bran and 6 of maize meal). This ration was always fed in the same proportions — 2 parts of concentrates to 1 part of alfalfa hay — and supplied throughout the experiment, which

was divided into four parts (see the appended table). During two successive periods the animal received quantities of this feed equivalent to a maintenance ration (period 1), and to a fattening ration (period 2). Fattening was then started, during which the steer gained 300 lbs. The experiment was continued in the reverse order, a fattening ration being first given (period 3), then a maintenance ration (period 4).

RESULTS. — These two successive comparisons of metabolism resulted in much data (grouped in a series of tables in the appendix) which lead to the following conclusions: —

1) *The digestibility* of the heavy ration is smaller than that of the light ration; it does not depend on the degree of fattening as corresponding rations were equally well digested before and after fattening.

2) *Urinary excretion.* — The percentage of nitrogen, carbon and energy lost in the urine was less on the heavy than on the light ration, and a little greater in the fattened than in the unfattened animal.

3) *The production of combustible gases*, both as compared with the total feed and with the digestible carbohydrates was notably less on the heavier than on the lighter ration, both before and after fattening.

4) *Value of the gross energy of the feed.* — In consequence of the smaller losses in urine and in combustible gases this loss was greater on the heavy than on the light ration; no difference in this respect was observed between the fattened and the unfattened animal.

5) *The additional heat* produced by the animal on the heavier rations was eliminated by means of evaporation of water.

6) *Energy expenditure consequent on feed consumption.* — The heat increment resulting from the consumption of a unit of feed was only a little greater in the fattened condition; consequently the *net* energy values of the feed and the percentages of metabolizable energy available for gain were slightly less in the fattened than in the unfattened animal.

7) The maintenance requirement was increased by 37 % after 3 months' fattening during which the live weight was increased by 300 lbs. This 36 % increase in basal katabolism was partly due to the greater body weight to be supported while standing, but the katabolism increases more rapidly than the weight or the body surface.

8) *General conclusion.* — The higher maintenance requirement and lower *fixed* metabolizable energy in the fattened animal are the principal factors responsible for slower gain in weight as fattening progresses.

324 - **Breeders of Purebred Stock in Queensland — Beef and Dairy Cattle.** — *Queensland Agricultural Journal*, Vol. VIII, pp. 247-248. Brisbane, November, 1917.

The Department of Agriculture and Stock of Queensland has published in this issue of the *Agricultural Journal* a revised list of breeders of purebred cattle, for the purpose of informing those who desire to improve their stock where the best cattle can be obtained in the State.

The Department of Agriculture and Stock takes no responsibility in relation to the entries in the list; but, when inquiries were first made, the condition was imposed that the entries were to be only of stock that had

been duly registered or that were eligible for registration in the different herd books. As the entries received were, in some cases, somewhat too confusing for proper discrimination, it has, therefore, now been decided that only such cattle as have been registered will be included. This list of breeders of pure bred stock in Queensland shows that all the principal breeds of cattle are represented and that they were registered in 15 different Herd Books, i.e., Milking Shorthorn Herd Book of Queensland; Ayrshire Herd Book of Queensland; Ayrshire Herd Book of Scotland; Holstein Cattle Club Herd Book; Holstein-Friesian Herd Book of Australia; Holstein Friesian Herd Book of Queensland; Jersey Herd Book of Queensland, Herd Book of the Jersey Cattle Society of Queensland; Commonwealth Standard Jersey Herd Book; Illawarra Dairy Cattle Herd Book of Queensland; Illawarra Herd Book of Queensland; Illawarra Dairy Cattle Association; Queensland Shorthorn and Australian Herd Books; Queensland Shorthorn Herd Book; Australian Hereford Herd Book; New Zealand Herd Book.

The total number of purebred males and females owned by these breeders may be discriminated as follows between the different breeds.

	Males	Females
Milking Shorthorns . . . . .	5	61
Ayrshire . . . . .	74	371
Holstein-Friesian . . . . .	22	77
Jersey . . . . .	35	224
Illawarra . . . . .	5	48
Shorthorn . . . . .	27	137
Hereford . . . . .	114	563

## SHEEP

325 — **Machine Sheep-Shearing in New Zealand.** — See No. 340 of this Review.

## PIGS

326 — **Feeding Pigs on Kitchen Waste.** — PRIME, T. F., in *The Journal of the Board of Agriculture*, Year XXIV, No. 10, pp. 1107-1109, London, January, 1918.

Finding no data on the amount of kitchen waste necessary to produce one pound of pork, the author carried out experiments on this subject. To this end he started in January 1917 to keep pigs on this food and continued during 48 weeks. Three pigs were bought on January 9, two of which were killed on March 5; four others were bought on March 10, one being killed on June 7; on September 1, five more pigs were bought. Throughout the experiment 6104 lbs. of food were consumed, and 870 lbs. increase in live weight were obtained, or roughly, 7 lbs. of kitchen waste (potato, vegetable and fruit peelings and waste, bits and remains of food) produced 1 lb. increase in live weight. During the whole period the only other food used was 28 lbs. of meal, given during a shortage of waste. The pork obtained was of excellent quality.

## SERICULTURE

327 — **New Silkworm Rearing Methods; the Acqua Small Trestle System and the Campbell Shelf System.** — ACQUA, C., Rearing early stage silkworms by means of a small trestle with immersed twigs, *Rend. onli dell'Istituto bacologico della R. Scuola Superiore di Agricoltura in Portici*, Vol. II, pp. 3-12, figs. 2; CAMPBELL, C., Some new methods for rearing silkworms, *Ibid.*, p. 23-29, figs. 2. Portici, 1917.

For some years, attempts have been made to diffuse the economic method of rearing employed in Friuli throughout Italy. This system consists

in giving the larvae, after the 3rd. or 4th. stage, leaves attached to the boughs, using horizontal hurdles or special trestles as supports. For the first stages, the Friulian system does not differ from these ordinarily used. The author has a system, by means of which the larvae can be reared on boughs from hatching. To preserve the leaves fresh and tender, and to avoid loss due to the rapid withering of the cut leaf, the lower ends of the branches are kept immersed in a small basin of water, placed on a shelf attached to the lower part of each side of a small trestle, some 20 in.  $\times$  20 in. square, (fig. I). A metal sheet is spread over the trestle, and covered with cardboard, strong paper, or even gauze. The small basin is provided with a stoppered opening, so that the water can be changed without moving the recipient. When the leaves are eaten, fresh boughs are placed with their ends in the water (which has been changed), care being taken to place them close to the old boughs; the young silkworms soon pass on to the fresh

Fig. I. — ACQUA trestle method.

leaves; the day after, the old boughs are removed. Four small trestles suffice for rearing 2 ounces (60 gm.) of eggs up to the end of the second stage; the system may be used for the third stage, by employing larger trestles. Thus, for 2 ounces (60 gm.) of eggs, a trestle, 6 ft. 6 in.  $\times$  6 ft. 6 in., would be used, divided in two by a small shelf on which a small basin is placed, as with the lower one. For the 5th. stage, it is useless to place the boughs in water, as the larvae eat the leaves before they have time to wither and losses due to withering are not to be feared. With this system there is economy of labour, a saving of leaves, and better hygiene, due to the suppression of litter.

The small trestle of Prof. ACQUA gave good results in the hands of private rearers, as well as at the Sericultural Institute of Portici.

Prof. CAMPBELL has introduced a slight modification into the system. The trestle devised by him is about 3ft. long and 1ft. 6 in. high; on the frame

is stretched a cloth which remains till the end of the season, when it is washed and replaced. At the foot of the trestle is the shelf on which is

Fig. II — CAMPBELL shelf method.

placed the basin, above which is a board perforated with holes to receive the ends of the mulberry branches ; with this device there is no fear of the larvae falling in the water and drowning, while the water is also protected

from dust. Prof. CAMPBELL is of the opinion that this system should become widely used, especially in southern Italy, where the high temperature and dry climate soon cause the leaves to wither and lose their freshness.

To restrict the space required so as to approximate that necessitated by the Friulian system, Prof. CAMPBELL has devised a system for rearing stages following the first one, and which consists of hurdles or supports (fig. 2) placed one above the other in pairs, 6ft. 6 in long and 3ft. 3 in. apart; the double series together thus being 6ft. 6 high. On each support are small shelves, each 2ft. wide and inclined inwards; the boughs are placed upright on these shelves, their tops being supported obliquely by transverse ledges.

The mulberry branches are placed successively on the shelves according to the development of the larvae, and the length of the branches available. In the 4th. and 5th. stages the branches can be placed up to the third shelves in measure as the branches are gradually stripped. The branches are first placed in one half of the trestle, and when this is quite full and the larvae have eaten all the leaves, the branches are placed in the opposite half well in contact and interlaced with the branches on which are the larvae, so that they can easily pass on to the fresh boughs.

As an alternative, both sides of the trestle may be used by slightly separating the branches on which are the larvae, and placing the fresh branches in the gaps between, when the first are completely eaten. The old branches are removed when the larvae have left them.

The oblique shelves prevent the larvae from falling to the ground or on the lower shelves, and also receive the excreta. At the end of the 5th. stages, the heath is placed in the upper half of the trestle and the larvae move into it of their own accord.

This system gives economy of space and labour, as well as better hygienic conditions due to the good ventilation.

**328 - On Some Cytological Data on the Phenomena of Parthenogenesis in the Silk-worm** (1). — LÉCAILLON, A., in *Comptes rendus des Séances de l'Académie des Sciences* Vol. 166, No. 4, pp. 180-181. Paris, Jan. 28, 1918.

The author gives the results of his investigations into certain fundamental points concerning the changes which taken place in the unfertilised egg.

1) The examination of consecutive sections of eggs which, towards the third day after being laid, began to turn from yellow to pink, showed that the development of the embryo had already reached the stage where the serum, amnios and embryonic sack were formed. and where the breaking up of the vitellus has already taken place. The stage at which colour begins to change is not a starting stage, but corresponds to an already advanced development. The appearance of the pink colour is due to the deposition of pigmented granules in the cells of the serous envelope against the vitelline membrane. This stage is exactly similar in the fertilised egg.

(1) See R. April, 1916, No. 427; Oct. 1917, No. 936; Nov., 1917, No. 1050; Feb., 1918, No. 197.

2) In unfertilised eggs which have not changed colour and have been laid a sufficiently short time for the cellular degeneration to be still visible, an intravitelline segmentation was observed similar to that taking place in the fertilised eggs of most insects, except that more or less premature cessation of development was manifest.

3) In unfertilised eggs which had kept their original yellow colour, but which were from 10 to 12 days old, cellular degeneration was much more marked than in the preceding case.

4) These facts confirm and extend those already given by the author in a preceding note (1), which showed that, in the eggs of *Bombyx mori* which do not change colour, important phenomena of development take place. The capacity for parthenogenesis in the silkworm, therefore, really corresponds to a quality proper to the female reproducing element and not to a property peculiar to eggs which change colour after being laid.

The earliest stages of degeneration observed in *Bombyx mori* which only correspond to a segmentation stopped very early seem in every way comparable to the rudiments of development observed in birds.

## FARM ENGINEERING.

### AGRICULTURAL MACHINERY AND IMPLEMENTS

329 - **The Work of a Tractor in Stony Soil.** — PLUCHET, E., in *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. III, No. 36, pp. 1037-1040. Paris, November 21, 1917.

The author advised the purchase of a 10-20 HP. tractor for a large estate at Eure-et-Loire, France, having a number of stony areas. The tractor was chosen, on the recommendation of M. RINGELMANN, from amongst those tested at Noisy-le-Grand (2).

Paraffin was used as fuel, being so much cheaper than petrol; heavy oils of at least 30° Baumé could also have been used. The tractor began work on uncultivated ground about July 15, 1917. For various reasons, such as bad weather, harvest work, holidays, etc., the tractor only worked 340 hours, or 45 days of 8 hours, from the above mentioned date up till the end of October. During this time 160.6 acres were worked to a depth of 7 to 8 inches (about 1 acre in 2.2 hours), in very stubborn and stony soil. In these soils, the usual implements and tools wear very quickly and the average work done by 1 man with 3 horses does not exceed 4 200 to 4 800 sq. yds. per day.

The 160.6 acres worked cost about £ 110. 3s. for fuel, lubricants, socks and new parts, repairs and upkeep. The working parts of the machine did not seem to have suffered, in spite of the difficult ground. The tractor was driven by the estate foremen; in spite of this, the author allowed the drivers the pay of 9½d. an hour; on adding, for the working hours £ 13. 12s. to the expenses, the total became £ 123. 15s. and each acre worked cost 15s. 5d.

(1) See R. Oct., 1917, No. 936 — (2) See R., November, 1917, No. 1051 and R. January 1918, No. 81. (Ed.)

The author has only been able to estimate very roughly the depreciation of the machine, etc. Supposing that the tractor, which cost £500, can last three years if well cared for, the depreciation would amount to about £13.18s. a month, giving say £48 13s. for the 3 ½ months of work. The total cost for the 160.6 acres would then amount to £172. 8s. or. 21s. per acre, which is very high for work at 7 to 8 inches deep, but little higher than the cost for the same work performed by animals.

This example again shows the advantage of machine cultivation and the great help it may afford under the present circumstances, even with imperfect machinery.

330 - **Cultivation Trials with a Moline Tractor, in Italy.** — TARCHETTI, A., in *Il Giornale di Riscicoltura*, Year VII, No. 22, pp. 278-282. Vercelli, November 30, 1917.

Cultivation trials with the combined Moline tractor (1) were carried out in ricefields, in October and November 1917, by the Machinery Section of the Experimental Rice-growing Station at Vercelli.

The first trials took place at Muleggio (Vercelli) in both ricefields and ordinary ones. The tractor drew a 2-furrow 12 in. plough, to which was fixed, according to the ricegrowers' wishes, an ordinary coulter as well as a skim coulter replacing the circular coulter.

The wheels were provided with 3 rows of cuneiform spikes projecting 4 in. beyond the tyre. In the ricefield the average speed when working at 6 to 7 in. was about 3 miles per hour; in the ordinary field the speed was 2 ½ miles per hour at a depth of 7 to 8 in. and a width of 24 in., which correspond respectively to 3 468 and 2 870 sq. yds. of surface covered per hour. These first trials gave quite satisfactory results.

The next trials were carried out at Castelmerlino (Vercelli) in a well-manured riceland, in good general condition, save one short and difficult strip which was very soft. Instead of spikes, the wheels were fitted with strakes projecting some 5 ins. The author gives the following results obtained one period of the trial: —

Duration of trial: 2 hrs., 4 mins., 20 secs., <i>i.e.</i> . . . . .	7460 seconds
Divided up as follows: —	
Duration of ploughing (average of 3 minutes per furrow of 618 ft. . . . .	3960 "
Duration of turning (average of 30 secs.) by towing . . . . .	660 "
	<hr/>
Total duration of the work. . . . .	4620 "
Optional stoppages for adjustments of plough, measuring, etc. . . . .	2840 "
	<hr/>
Total time. . . . .	7460 "
	<hr/>
Average depth of ploughing . . . . .	7 to 8 in.
Area ploughed: — average furrow length . . . . .	618 ft.
Total furrow width . . . . .	50.15 ft.
Area ploughed during the trial . . . . .	2994.2 sq. yds.
Petrol consumed during the trial 2.42 galls. equal to 16.94 lbs. (density 700)	

(1) See R. 1917, No. 941. (*Ed.*)

The conclusions are:

Petrol consumed (1)	{	per acre	14.3 lb.
		" hour.	8.16 lbs.
Area ploughed per hour . . . . .			2762 sq. yds.

Using these results, the author calculates the cost of mechanical ploughing per day: —

The **MOLINE** tractor with a 2-furrow plough and accessories costs £ 600 in Italy; assuming that the petrol costs 7*d.* a lb. and that a tractor is used on 80 days during the year, the daily cost would be:

Petrol for 10 hours work 88 lbs. at 7 <i>d.</i> a lb. . . . .	51 <i>s.</i> 4 <i>d.</i>
Driver's wages . . . . .	8 <i>s.</i>
Lubricating oil . . . . .	3 <i>s.</i> 2 <i>d.</i>
Interest and depreciation at 5% on £600 and assuming the machine to last 10 years. — say . . . . .	20 <i>s.</i>
Insurance, various expenses . . . . .	6 <i>s.</i> 4 <i>d.</i>
Daily cost . . . . .	88 <i>s.</i> 10 <i>d.</i>
that is, one acre costs 14 <i>s.</i> 9 <i>d.</i>	

The author observes that machine ploughing is fairly costly but under present conditions, given the scarcity of labour and draught animals, it is important to produce as much as possible.

331 — **The Dessaules Tractor.** — **RINGELMANN, MAX**, in the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale*, Year CXVI, Vol. CXXVIII, No. 6, pp. 476—478, fig. 1. Paris, November-December, 1917.

The **DESSAULES** tractor took part in the 1917 trials at Noisy-le-Grand (2), France; the test model was made by **M. H. DESPLAND**, of Levallois-Perret, Seine. The appended schematic figure shows the type of machine, which has 2 driving and steering wheels *a* and *b*, which can turn obliquely in the directions *a'* and *b'* or *a''* and *b''*; these wheels are placed one behind the other, transverse equilibrium being provided for by two pivoting wheels *c* and *d*, mounted on forks, fixed to a beam *tt'* attached to the upper part of the frame, whose plan is shown at *h*. The engine *m*, placed low down between the driving wheels, chain-drives an intermediary shaft just above it; the shaft drives, through 2 chains, two axles placed above the wheels *a* and *b*; the driving-wheels are driven by 2 chains-drives from these axles; the gearing thus includes 5 chains, which should not run at the same speed, as in the experimental model. The driver's seat being placed either at *s* or *s'*, the machine can move either in the direction *f* or *f'* in a turnip-field, without turning on the furrow; the hauling attachment is at *h*, on *s* or *s'*.

(1) The petrol consumption on normal work would be 8 8 lb per hour and 16 lb per acre.

(Author)

Plan of DESSAULES tractor.

332 - **The Wyles Motor Plough.** — I. *The Agricultural News*, Vol. XVI, No. 406, p. 357. Barbadoes, November 17, 1917. — II. FRIER, VICTOR, in *Le Génie Rural*, Year X, No. 76, (New Series, No. 16), pp. 11-15, figs. 5. Paris, 1917.

According to information received by *The Agricultural News* from the Secretary of the Food Production Department of the Board of Agriculture and Fisheries, England, it would appear that the WYLES motorplough is well suited for work in orchards and on small farms, while being unsuitable for large farms.

This English-made motorplough is guided by handles by a man walking behind; the 2-furrow plough can be lifted so as to clear the headlands, as the weight of the machine is well balanced about the front axle.

All parts of the machine are standardised and can easily be replaced.

The chief points of the WYLES motorplough are as follows:

1 cylinder vertical 11 HP engine.

Gears completely enclosed and working in an oil bath; 2 forward speeds are provided; a reverse is unnecessary.

Wheels — diameter, 2 ft. 9 in.; tyre, 7 in. wide; length, 12 ft. 6 in.; width, 2 ft. 9 in.; height, 4 ft.

Including a 2-furrow plough, it weighs about 20 cwt.

This motorplough, though possibly not very suitable for strong sugar-cane fields, would work very well in light soils, and in cotton fields, etc. It is made by the WYLES MOTOR PLOUGHS CO. LTD., of Manchester.

II. — The WYLES patent, No. 464 699 (1913), described in *Le Génie Rural*, includes a new device for the steering and general control of wheeled agricultural machinery, such as motorploughs, etc. The cultivating implement may be varied as required. The machine is easily steered and becomes quite automatic (provided that the engine has a regulating device); it requires no attention save in turning at the headlands.

Another WYLES patent, No. 477 074 (1914), concerns improvements of a mechanism regulating the wheels which uses the power of the engine, driving the carrying wheel or wheels, to lift the body of the machine automatically.

Designs are given with the patents, showing details of the inventions.

333 - **The Blanchard (1): Double Brabant Windlass Plough.** — RINGELMANN, MAX, in the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale*, Year CXVI, Vol. CXXVIII, No. 6, pp. 473-476, 4 fig. Paris, November-December, 1917.

The BLANCHARD double-brabant plough is of the windlass-plough type; it carries the engine and 2 reeling drums, on each of which is rolled a cable whose end is anchored in the furrow.

An Ardennes farmer, M. BLANCHARD has invented the machine, the model tried at Noisy-le-Grand, France, having been made by M. E. ALLONGÉ of Paris. Figure 1 shows the general view of the machine, while figure 2 shows its plan. In the latter various details can be seen: — the machinery fixed to the support of a double-brabant plough; the beam *a*; the ploughs *b* and *b'*; the furrow wheel *c* running in the furrow *x*, and the land-wheel *c'* running at *x'*; the grounding screw *d* and the stilts *e* that carry the locking mechanism; the stays turning round the beam *a* fixed to the support *ee'*.

The machinery fixed to 2 bars of the wheels *cc'* includes a small 3-4 HP. single-cylinder engine *A*; the cooling of the cylinder ribs is provided for by a lateral fan; the petrol tank is placed on a shelf supported at *f*. The engine shaft is connected by a chain drive *g* to an intermediary shaft *B*; the windlasses *C* are mounted on a shaft driven by a chain *i* from *B*; in these 2 drives, reducing the engine-speed, the tension of the chains are regulated by rollers *h* and *j*. The 2 windlasses *C* can each be geared up to the shaft on which they are mounted when they pull the plough by rolling up the cable *m*, or put out of gear when the cable *n* is unrolled behind on the untouched strip *x'*. In the machine tested by the author, the cables, when used for traction, pass between guide rollers *l*, which will be replaced in the final model by an automatic winder.

In the trials, the greatest traction could not be more than 770 lbs, equal to the breaking point of the cable. When the plough moves in the direction *r*, it hauls on the cable *m* and pays out the return cable *n* behind. When at the end of the cable, the driver puts the windlass out of gear, removes the cable *m* from the guides *l*, tips and turns the plough so as to place it in position to open the new furrow, fixes the hook of the cable *m* on the anchor chain in the furrow; he then passes the cable *n* between the guide *l* of the second windlass, which he puts in gear, when the plough moves in the opposite direction to *r* to the other headland, when the same process is repeated. The driver walks alongside the machine.

The cables are simply laid down, and are not damaged in any way by rubbing. The anchorage for each cable consists of a chain some 16 ft long,

held down by stakes ; the cable hook engages in one of the links of the chain, and, each time the plough arrives at the headland, the hook is moved along the anchor chain to a width equal to about twice the furrow width.

BLANCHARD *Double brabant windlass plough.*

Fig. I — View of the machine.

Fig. II. — Diagram of the machine.

334 - **The Shubert Weed and Sprout Destroyer.** — *Farm Implement News*, Vol. XXXV No. 49, pp. 36, 2 figs. Chicago, December 6, 1917.

The extermination of weeds, sprouts, etc., with the usual machines is  
*The Shubert Weed and Plant Destroyer.*

Fig. I. — Side view.

Fig. II. — Rear view.

for that purpose is very difficult and even impossible on stony and stumpy land.

As is shown in the appended figures, the machine is provided with a revolving cross bar to which are attached a number of chains ending in cutting blocks. Power for revolving the chains is derived from one wheel and transmitted by suitable gearing. The chains are whirled at high speed, the velocity being such that any plant struck is reduced to shreds and spread over the ground. Ability to work among stumps and stones is due to the flexibility obtained by using chains, which simply work themselves round obstructions. The cutting ends do not reach the ground, so that grass is left uninjured.

The machine weighs about 850 lbs. ; the wheels are about 4 ft. high and the space within the angle iron frame about 4 ft. square. It is made by the SHUBERT SPROUT MOWER COMPANY of Richland Mo., U. S. A.

335 - **Copra Driers.** — See No. 346 of this *Review*.

336 - **Investigations of Irrigation Pumping Plants, in Montana, U. S. A.** — MURDOCK, H. E., in: I. *University of Montana. Agricultural Experiment Station, Circular No. 60*, pp. 37, fig. 17. Bozeman, Montana, January, 1917; II. *Ibid.*, *Bulletin No. 115*, pp. 127—148. fig. 6, tables 5. Bozeman, Montana, January, 1917.

I. In the United States many irrigation pumping plants have been installed without sufficient forethought and thus have resulted in failure.

In studying the question of installing an irrigation pumping plant, special attention should be paid to well prepared plans, proper types of pumps, cost of plant, maximum head that can be lifted, market conditions and prices of crops to be grown, etc. Crops grown with pumped water should require little water and give high crop value for each acre, while the plant installed should give the maximum running economy with the minimum maintenance charges.

The author considers the various types of pumps ; centrifugal pumps, the horizontal type of which is most adapted for lifting not more than 30 ft., while the vertical type is suited for deeper wells of 3 to 6 ft. diameter ; turbine pumps, for deep wells (250 ft.) of small bore (12 to 30 in.) ; plunger pumps, for deep wells of small bore (3 in.). It should be noted that irrigation from deep wells is very dear, and only pays for high-priced crops. Plunger pumps are of very small capacity thus being most suited to filling reservoirs till enough water is stored for a day's irrigation.

Irrigation pumps can be driven by windmills, steam, gasoline and oil engines of the portable, stationary and tractor types. Windmills have long been used for this purpose ; if well cared for, they last a long time ; they usually drive plunger pumps. Using gasoline for pumping is expensive, and to utilise the cheaper, heavy oils the fuel oil engine has been rapidly perfected. The heavy oil engines have the advantage that with a little adjustment they can use any liquid fuel of a higher grade than that for which they are designed. The operation of a steam engine requires a more skilled mechanic than does an internal combustion machine. The laws of Montana require a licensed engineer to operate a steam engine. There is a

large amount of lignite and soft coal in Montana will could furnish a source of cheap power. Electric motors have many advantages; many plants only require a visit once every 24 hours for oiling and other attention.

Curves are given to help in choosing a pump, use being made of various conditions of speed, head, discharge and power. A few of the most common engine and pump troubles are described as well as methods for remedying them.

As regards the cost of operating pumping plants, the author assumes it as being directly proportional to the lift. For a pumping installation driven by a gasoline motor, the proportional annual cost for the gasoline was 58.7 %, 19.7 % for the irrigator and operator, 15.7 % for interest and depreciation, 5.9 % for lubricating oil; for a plant driven by a paraffin motor the figures were: — 46 % for paraffin, 25.8 % for the irrigator and operator, 20.5 % for interest and depreciation, 7.7 % for lubricating oil; these figures vary very greatly, but can be much reduced by giving as much care to the irrigation as to the pumping plant.

II. The Agricultural Experiment Station of the University of Montana has tested a number of pumps and engines, in order to throw light on the problems of pumping for irrigation. The tests were partly carried out in the University laboratory and partly with plants actually working.

The pumps tested in the laboratory were: CASE plunger pump; FRIEND motor pump; GOULDS Pyramid plunger pump; BYRON JACKSON vertical centrifugal pump; American 7-in. vertical centrifugal pump. The pumps tested in the field were all of the horizontal centrifugal type and were: 1 Morris 18-in.; 1 American 10-in.; 1 GOULDS 8-in., 1 Rumsey 6-in.; and 2 GOULDS 6-in. pumps.

The following engines were used in the laboratory tests: — Case 75 HP. steam tractor; International Harvester Company 45 HP. petrol-paraffin tractor; Case 36 HP. steam roller; Fairbanks-Morse 5 HP. vertical petrol engine; International Harvester Company 5 HP vertical petrol engine; Friend horizontal 4 HP. petrol engine; Int. H. C. I HP, paraffin-engine, Fuller & Johnson 3/4 HP. vertical petrol engine.

The following engines were used in the field: Case 75 HP. stationary steam engine; Fairbanks-Morse 65 HP. stationary steam engine; Fairbanks-Morse 20 HP. horizontal paraffin engine; Galloway 15 HP. horizontal petrol engine; Field 12 HP. horizontal petrol engine; Galloway 8 HP. horizontal petrol engine.

To measure the water discharged, a 2-ft. CIPOLLETTI weir was used. For the field tests a temporary rectangular weir was used when practicable; for smaller currents a current meter was used. In tests for power consumption a PRONY brake was used.

The results of the tests are shown in 5 tables which give: the HP. of the engines, the head of water, discharge, the various types of pump tested, the water lift, consumption of fuel, and the quantity of lubricating oil used.

The results of the laboratory tests bring out forcibly the inadvisability of using any chance combination of power and pump that may be available. They also indicate what kind of combination should be made to secure an efficient plant. Thus if a 45HP tractor is used to drive a 7-in. vertical pump, with a 50-ft lift, the tests show a fuel consumption of about 0.4 gallon per foot acre-foot, which is very satisfactory. The same tractor driving a 5-in. vertical pump consumes 50 % more fuel; with a 3-in. pump there is

a fuel consumption of about 2.5 times the amount required for the largest pump. If the lift is 25 ft., a larger pump than those tested should be used with such a tractor, for the fuel consumption would be about 50 % greater than that for the 50-ft. lift.

To lift 10 feet, the tractor with the largest pump consumed 1.22 gallons of fuel per acre-foot. With a much larger pump designed for a low lift, less fuel would have been consumed. In tests with a 5HP. engine, driving a 3-in. and 5-in. pump respectively, the fuel consumption was about 0.7 gallon per foot acre-foot.

These results indicate the necessity for careful designing of pumping plants and proper operation of the plant after it is installed.

	1 248 034	Agricultural implement.
	1 248 194	Cultivator.
	1 248 257	Revolving harrow.
	1 248 945	Land roller.
	1 249 103	Attachment for stalk cutter.
	1 249 395	Self cleaning harrow.
	1 249 447	Tractor plough.
	1 249 523	Two-way motorplough.
	1 249 524	Reversible tractor plough.
	1 249 555	Combined harrow and cleaner.
	1 250 013	Gang plough.

#### *Irrigation.*

British India	3 201	Gravity water elevator.
Canada	179 444	Ditch plough.
United States	1 248 271	Regulator plough.

#### *Manures and Manure Distributors.*

France	485 455	Ammonia produced by catalysis for making simple and complete manures.
United Kingdom	111 254	Method of treating the soil to improve its productivity by means of spraying water heated at 180-210° F.
United States	1 247 001	Attachment for lime spreader.
	1 247 631 — 1 247 703	Manure spreaders.

- 1 247 632 Wide spread attachment for manure spreader.  
 1 248 032 Spreader for fertilizer distributor.  
 1 248 303 Straw spreader.

*Drills and Seeding Machines.*

- Denmark 22 475 Potato planter.  
 United States 1 247 007 Anchor for check row planters.  
 1 247 075 Clutch for maize planter.  
 1 247 738 Planting mechanism.  
 1 247 744 Combined disk lister and planter.  
 1 247 763 — 1 248 351 Seed planters.  
 1 248 717 Maize planter.  
 1 249 067 Lister plough.

*Various Cultural Operations.*

- United States 1 246 896 — 1 247 764 Cultivators.  
 1 247 246 — 1 248 160 Cotton choppers.  
 1 248 010 — 1 249 569 Weeding ploughs.  
 1 248 231 Riding cultivator.  
 1 248 365 Machine for pulling cotton plants.  
 1 248 706 Vineyard disk plough or cultivator.  
 1 248 914 Hand cultivator.

*Control of Diseases and Pests of Plants.*

- France 485 274 Improvements in powdering machines.  
 Switzerland 76 646 Trap for rats, mice.  
 United Kingdom 111 044 Device for destroying insects.  
 111 142 Vermin proof room for preserving fruits.  
 United States 1 248 751 Grass and weed cutter.  
 1 249 988 Potato bug killer.

*Reapers, Mowers and Harvesting Machines.*

- British India 3 171 Improvements in or relating to instruments for tapping.  
 India rubber producing and like latex yielding plants.  
 Canada 179 060 Sheaf carrier.  
 179 090 Grain binder.  
 179 277 Sheaf shocker.  
 179 297 Harvester mechanism.  
 Switzerland 76 644 Cherry picker.  
 United Kingdom 111 052 Reaping and mowing machine.  
 United States 1 246 234 Gang lawn mower.  
 1 246 951 — 1 246 963 — 1 247 005 — 1 247 943 — 1 249 935 Shocking  
 machines.  
 1 247 070 — 1 249 914 Harvesters.  
 1 247 387 Cotton picking machine.  
 1 248 591 Corn husking machine.  
 1 249 295 Seed gathering attachment for mowers.  
 1 249 445 Peanut harvester.

*Machines for Lifting Root Crops*

- Denmark 22 464 Tool for topping and lifting turnips by hand.  
 22 560 Combined potato digger and elevator  
 22 616 Turnip topping and lifting machine

- United States    1 246 811 Beet harvester.  
                     1 247 813 Potato digger.  
                     1 248 330 Beet topping machine.  
                     1 248 379 Beet digger.  
                     1 249 911 Frame for beet harvesting machine.

*Threshing and Winnowing Machines.*

- Canada            179 093 Grain cleaner.  
                     179 105 Grain grader and cleaner.  
  United States    1 246 949 Grain saving device for threshing machines.  
                     1 249 663 Feeder for grain separators.  
                     1 249 966 Grain separator.

*Machines and Implements for the Preparation and Storage of Grain, Fodder, etc.*

- British India     3 178 Rice huller.  
  Denmark         22 476 Straw binder.  
                     22 568 Combined straw gatherer and binder.  
  United Kingdom   110 556 — 111 307 Baling presses.  
  United States    1 246 569 — 1 246 759 — 1 248 753 — 1 249 505 Hay presses.  
                     1 246 994 Stacker.  
                     1 247 233 Hay gathering and baling machine.

*Steering and Traction of Agricultural Machinery.*

- Canada            179 228 Wagon mechanism.  
  United Kingdom   111 242 Caterpillar tractor.  
  United States    1 246 443 Tractor wheel.  
                     1 246 603 — 1 249 996 Tractors.  
                     1 246 777 Whiffle tree.  
                     1 247 073 Traction machine.  
                     1 248 036 Tong truck.  
                     1 248 599 Steering device for tractors.  
                     1 248 693 — 1 249 059 Farm tractors.  
                     1 249 166 Caterpillar tractor track.  
                     1 249 424 Draft connection for tractor.

*Feeding and Housing of Livestock.*

- United Kingdom   110 853 — 111 214 Horse shoes.  
  United States    1 246 751 Collapsible hog feeder.

*Poultry Farming.*

- Switzerland       76 645 Transportable poultry house.  
  United Kingdom   111 208 Incubator.

*Bee Keeping.*

United Kingdom	110 641	Centrifugal pump.
	110 851	Wind motor.

## RURAL ECONOMICS.

338 - **Size of Farm Business.** — JOHNSON, O. R. and FOARD, W. E., in *University of Missouri College of Agriculture, Agricultural Experiment Station Bulletin* No. 140, pp. 1-40. Columbia, Missouri, April, 1917.

This study of the size of farm business was made by means of a Farm Management Survey in the Western part of Johnson County, Missouri.

The farm management method of securing data includes the obtaining of estimates of all receipts and expenses on each farm in a district or region, for a year, and the investment at the beginning and close of the year. Data are secured concerning methods, practices and social conditions of the region. The incomes of all farms are then ascertained and certain factors which have to do with the success of the business are calculated. Then the farms are grouped according to size, capital, labour income and other factors.

*The Region Studied.* — The region selected for this study which includes four townships in the western part of Johnson County, is typical of a large section of the State. The soil, climate, railways, roads, markets, land values, size of farm, and type of farming are similar to those found in many sections of central Missouri. The average crop yields for the region in 1912 were: maize, 35.4 bushels per acre; wheat, 17.8; oats, 28; hay, 1 ton. The average price of maize, was 45 cents, wheat 85 cents, oats 35 cents and hay \$ 12.

*Size of farms, their percentage distribution and proportion of tillable land.* — The farms used were first divided according to number of acres operated, the percentage of tillable and pasture land, and of waste land as shown in Table I. This gives a general idea of the distribution of the farms in the size groups. The average size of the farms of the region was 137.8 acres.

TABLE I. — *Percentage distribution of farms by size and proportion of tillable land.*

Size group acres	Farms	% of total	Tillable land %	Pasture land %	Waste %
< 40 . . . . .	47	7.0	82.2	26.1	6.0
41- 80 . . . . .	149	22.3	86.9	32.1	5.6
81-120 . . . . .	151	22.6	80.5	31.3	5.0
121-200 . . . . .	191	28.6	86.4	33.5	3.5
201-400 . . . . .	106	15.9	81.5	37.5	3.2
> 400 . . . . .	24	3.6	87.4	47.1	2.7
Total . . . . .	668	100.0			

The distribution of investment in the various groups is shown in Table II. The proportion of investment in real estate increases on the larger farms. Under present conditions the market value of land is gradually increasing but the man on the small farm gets less benefit from this increase in value than the man on a large farm, because a smaller percentage of this total capital is invested in real estate.

TABLE II. — *Distribution of Investment on 668 Farms.*

Size group	Farms	Real estate	Machinery	Live stock	Supplies	Cash	Total
< 40 . . . . .	47	76.6 %	3.3 %	16.9 %	2.2 %	1.0 %	100
41- 80 . . . . .	149	78.9	2.5	15.5	2.0	1.1	100
81-120 . . . . .	151	81.8	2.2	13.5	1.7	0.8	100
121-200 . . . . .	191	81.3	2.2	13.7	2.2	0.6	100
201-400 . . . . .	106	83.2	1.9	12.3	1.8	0.8	100
> 400 . . . . .	24	83.6	1.6	11.9	1.7	1.2	100

Table III gives the number of various classes of livestock, horses, cows, brood sows, and total animal units (1), on the farms of different sizes, the crop acres per animal unit and the efficiency with which the farmer uses his own labour and equipment on the various sized farms. The operator of a small farm grows 15.9 acres of crops for each workman, 7.3 crop acres for each work horse and 20.9 crop acres for each hundred dollars invested in farm machinery. Against this the 201-400 acre farmer grows 67 acres of crops for each workman, nearly 17 acres for each horse and 35 acres for each 100 dollars worth of machinery. The workman has multiplied his

(1) **DEFINITION OF TERMS.** An *Animal unit* is a horse, cow, five mature hogs, or seven mature sheep; two young animals are regarded as equal to one mature animal of the same kind, on the basis of feed and manure produced. This unit is only approximate at best.

A *productive work unit* is a 10 hour day of productive work, done by either a man or a horse. It includes work on live stock, on farm crops, or on the improvement of land; but not on work stock, on the repairs of fences, buildings, and machinery; or on anything else included in the maintenance of the farm.

A *crop index* of 97 simply means that the yield per acre of all crops on this farm or group of farms is 97 % as great as the average yield of the groups of the region.

*Labour income* is the farmer's net return after paying from his gross income all general running expenses, including also interest at 5 per cent, depreciation, and wages for hired labour and members of his family, but excluding household expenses. (*Ed.*)

efforts by four, the work horse has doubled the amount of work which he does, and the cost of using equipment has been reduced by nearly half. This will explain in part some of the results which will be given later.

TABLE III. — *Animal Units, Labour Equipment and Size of Farms.*

Size group	Horses	Cows	Sows	Total animal units	Crop acres per		Average size acres	Crop acres per		
					animal unit	animal unit, except horses		Man	Horse	\$ 100 equipment
< 40 . . . . .	2.3	2.8	1.0	4.8	3.48	6.68	26.6	15.9	7.3	20.9
41-80 . . . . .	3.5	2.4	1.8	10.6	3.29	4.13	64.6	25.9	8.4	22.0
81-120 . . . . .	4.2	3.0	3.8	13.4	4.47	6.52	103.3	49.2	14.3	33.0
121-200 . . . . .	5.8	4.6	3.1	21.0	4.20	5.81	159.2	58.9	15.3	33.1
201-400 . . . . .	8.0	6.6	5.7	31.8	4.25	5.68	243.5	67.7	16.9	35.1
> 400 . . . . .	10.4	14.9	10.5	53.8	3.88	4.84	459.6	77.2	21.2	35.6

The same general condition is shown in Table IV, giving the number of productive work units (1) per man and horse on farms of various sizes. This table shows that the man on the smallest farm does about a third as much work as the man on the farm of the next size, while the horse on the larger farm does one and a half times as much as the horse on the smallest farm. The labour income varies in the same direction.

TABLE IV. — *Productive Work Units and the Size of Farms.*

Size group	Average size acres	Work units		Labour income
		per man	per horse	
< 40 . . . . .	26.6	65.4	32.0	\$ 146
41-80 . . . . .	64.6	110.3	31.0	227
81-120 . . . . .	103.3	148.7	43.5	313
121-200 . . . . .	159.2	167.1	44.3	525
201-400 . . . . .	243.5	213.0	48.2	711
> 400 . . . . .	459.6	171.5	48.8	999

In Table V it will be found that the receipts per acre decrease as the farm increases in size up to the 120 acre farms, above that there is practically no variation. The farmer on 64 acres has about as much expense and about the same receipts per acre as the man on the 240 acre farm. This gives them about the same net income per acre. When this net income is multiplied by the number of acres operated, it is understood why the large farmer gets the larger labour income.

In comparing crops yields it is found that except for the 26.6 acre farm the yields gradually increase as the size of farm increases. This is shown in Table VI, the crop index (1) being the average yield of all crops in terms of per cent; the average yield of four of the more important crops is higher on the larger farms.

(1) See notes page 381.

TABLE V. — *Size of farm and Receipts and Expenses per Acre.*

Size of group	Receipts		Expenses		Net income per acre
	per farm	per acre	per farm	per acre

Labour income . . . . .	146	227	313	525	711	999

The results shown in the foregoing tables must lead to the conclusion shown in Table VII, giving the capital, receipts, expenses, and labour income

of the various groups. The farmer on the 26 acre farm has only \$ 2447 capital and gets a farm income of \$ 268. The farmer on the next group has \$ 5362 capital and gets a farm income of \$ 495. The farm incomes gradually increase until the larger farm is reached where the farm income is almost \$ 3000, giving a labour income of approximately \$ 1000.

Table VIII shows in a different way the relative profitableness of labour put in on live stock and also on cash crops, on the various sized farms.

TABLE VIII. -- *Returns per Days' Work on Crops and Stock Sold.*

Size of farm	Work done		Crop receipts		Net stock receipts	
	Crops Days	Stock Days	Total \$	Per day \$	Total \$	Per day \$
< 40 . . . . .	9.90	99.70	38.90	3.93	140	1.41
41- 80 . . . . .	23.50	159.40	109.80	4.67	323	2.03
81-120 . . . . .	38.27	244.93	171.00	4.49	505	2.06
121-200 . . . . .	65.82	312.18	326.00	4.96	812	2.65
201-400 . . . . .	128.70	458.65	733.00	5.70	1 056	2.30
> 400 . . . . .	177.90	539.70	1 278.00	7.18	3 228	4.13

The table in general shows a gradual increase in wages per day's work from the small to the large one. In preparing this table, all labour on crops sold was charged to crops, and all labour that was put in crops that were fed was charged to the live stock, after the labour of growing crops for work stock and the crops fed work stock was taken out of the total.

In general it shows that the farmer received half the wage in handling live stock that he received for growing cash crops. This does not mean, however, that he should devote all his efforts to growing cash crops, but lends emphasis to the fact that while a cash crop is often more profitable than a crop fed to live stock, when figured in terms of daily wages, yet the live stock enterprises will furnish labour throughout a much greater portion of the year, thus making the total wage at the close of the year much larger. A man is kept busy with his live stock during rainy weather and all winter when cash crops will furnish no labour at all. It can readily be seen from this table, however, that it will probably give him a more desirable system to have some cash crops in combination with live stock enterprises.

Table IX gives the net receipts from crops and stock and their percentage distribution between the various crops and various classes of stock.

TABLE IX.

Size of farm	Farms	Net receipts from		Percentage from crops	Corn	Wheat	Oats	Hay	Cattle	Hogs	Sheep	Poultry
		Crops	Stock									
		\$	\$	%	%	%	%	%	%	%	%	%

As the size of farm increases, the importance of corn as a money crop decreases and the importance of wheat and hay increases. In general as the size of farm increases the importance of cattle and hogs increases also, but the receipts from hogs increase more rapidly than the returns from cattle. In the first three groups, the returns from cattle are in the form of dairy products almost entirely, while on the larger farms the returns are often in the form of beef, dairy products being of less importance. Considering the social side of the farm business, on various-sized farms, some interesting facts were brought out. The family living on the small farm costs about \$ 62 per person, while on the large farm \$ 104 a person is spent. The large farmer spends more than four times as much for religious purposes as does the small farmer. The relative importance of cash expenses, produce, and other expenses of family living does not differ widely on the small and the large farm. Of the family living expense, 57 per cent. is a cash item; about 40 per cent. is produce furnished by the farm and the remainder is miscellaneous expenses.

After this discussion of the farm business measured by the number of acres farmed, the writers turn to the study of the influence of various amounts of capital invested on the labour income in the various groups. The following facts were brought out from this study. The labour income, on a certain sized farm, is limited by the capital investment. Some farms are too heavily capitalized and others do not have enough capital invested. The most successful farms in each group have an investment of from \$ 70 to \$ 95 per acre. The farmer with a low capital investment (\$ 54 per acre) sells more crops (50.3 % of receipts from crops) and gets lower yields (94.3 % crop index) than either of the other classes. The man with too high an investment per acre (\$ 148 per acre) does not sell enough crops (73.3% of receipts from crops), nor are his yields high enough to warrant his excessive investment (106.3 crop index); consequently his labour income is low. The man with a low capital investment per acre, does not keep much livestock and gives most of his time to crops. The man with a high capital investment per acre, is fairly heavily stocked and gives only about half his time to crops. The farmer who is making the best income gives about 60 per cent. of his time and about 94 per cent. of his horses' time to the production of crops.

The man with a low capital investment per acre, is giving so much attention to grain farming that his system does not give him enough productive labour. Where the capital is larger, the farmer is able to keep more livestock and thus secure more regular employment. This influences his labour income to quite an extent.

The work horse works harder on the farm with less capital per acre, but this difference in the amount of work which the horse does, does not offset the other advantages of the diversified or stock farming system, which the man with more capital is able to practice on a given area.

Considering the value of land it was found that the value per acre of land does not vary uniformly with the productivity of the soil. The yields increase as the value per acre increases up to \$ 60 to \$ 80 land. Above this

point the increase in yield in much less rapid than the increase in market value. The labour income reaches its highest point on the \$60 to \$80 land. After that the income begins to fall.

The profitableness of a certain farm is also influenced by the amount of productive labour done. It is easily possible for a 160-acre farm to support no larger business than an 80-acre farm. A system which furnishes from 2 to 2.3 days productive man labour per acre pays the largest labour income.

The profitableness of a certain-sized farm is also effected by crop yields. The labour income on a farm increases uniformly as the crop yield increases.

**339 - Government Lands, Leased Lands and Alienated Lands in Australia.** — *The Pastoral Review*, Vol. XXVII, No. 12, pp. 1137. Melbourne, December 15, 1917.

According to official returns there were to the end of June, 1916, in Australia, 105 422 000 acres of land belonging to private owners, while a further 56 096 000 acres were in process of being sold by the Government to private owners.

Then there were 893 054 000 acres leased, or held under various forms of tenure, and 849 159 000 acres of vacant Government lands, including roads and reserves. The position in each State is as follows: —

	Fully Alienated. Acres	Alienation Proceeding. Acres	Leased. Acres	Unoccupied. Acres
1 New South Wales . . . . .	40 363 316	19 409 656	118 865 868	19 415 580

**340 - Machine Sheep-Shearing and Lack of Labour in New Zealand.** — BRUCE, J. L., in *The Journal of Agriculture, New Zealand Department of Agriculture, Industries and Commerce*, Vol. XV, No. 3, pp. 134-135. Wellington, September 20, 1917.

Most of the New Zealand owners of sheep realise the advantages of the mechanical shearer, which permits shearing to be carried out more rapidly and more perfectly. Under present conditions it is becoming more and more difficult to find good shearers, and it is especially the small owners who meet with the greatest difficulties. The problem to be solved is whether it is advantageous for each herd owner to possess a mechanical shearer. The co-operation of small owners for the use of one mechanical shearer, as has been advocated, though perfect in theory, is not easy in practice. Each owner of at least 200 sheep should have his own mechanical shearer. Such an apparatus, with a 1 ½ HP motor costs £ 110 (motor, £ 50, plant £ 60). As the use of a machine allows, at the first shearing, a wool surplus which the author estimates at £ 10, and as the value of wool is now 55 % higher than it was in 1913-1914, a yield of from 8 lb. to 9 lb.

would pay half the cost of installing the machinery from the first season. A larger motor, preferably of 4 HP, would be more satisfactory, even for a small herd, for besides shearing, it could also be used for working a chaff-cutter, a pump, etc.

The reduction of labour is of the utmost importance in the present crisis, and in New Zealand, which is essentially agricultural, mechanical shearing is sure to play an important part.

## AGRICULTURAL INDUSTRIES.

341 - The Autolysis of Yeast and the Influence of Its Products of Proteolysis on the Development of Yeast and Lactic Bacteria. — VANSTEENBERGE, P., in the *Annales de l'Institut Pasteur*, Vol. XXXI, No. 12, pp. 601-630, Tables VII. Paris, December, 1917.

Experiments made by the author at the Microbiological Laboratory of the Higher Technical School of Delft (Holland), using: — 1) pressed beer and distillers' yeast; 2) various lactic ferments. The following results were obtained:—

After the death of the yeast cell, it loses its water, becoming much smaller. When the dead yeast has retained its fermentative, especially its proteolytic, activity, the yeast "liquefies", after a time varying with the temperature. The optimum temperature for the endotryptase is from 45-50° C. and the maximum at 53° C. The optimum for autolysis of the living yeast tested was from 48-50° C.

The increased acidity to litmus or phenolphthalein up to a certain fixed degree and the crystallisation of the tyrosine may be taken to show the good progress and end of the autolysis.

Yeast water, obtained by boiling fresh yeast in water, only contains  $\frac{1}{3}$  of the total nitrogen of the yeast. A preliminary autolysis for 23 hours at 48 to 49° C., changes all the nitrogen into soluble nitrogen not coagulable by heat. Autolysed yeast water is a better food for yeast and lactic bacteria than yeast water obtained by simply boiling. Apart from the quantity, the quality of the nitrogen is greatly improved by autolysis.

In autolysed yeast water of the strength of 20 gm. of yeast to 100 cc. of water, there are products that are unfavourable to the growth of the yeast; this harmful influence is removed on dilution.

Amongst substances acting in this way, tyrosine and leucine may be considered as two of the chief products of autolysis.

Leucine is still favourable at the strength of 0.08 gm. %, but completely stops development at 0.66 gm. %. Tyrosine is favourable up to 0.05 %, but beyond that strength is harmful. Asparagine as harmful beyond 1 %.

These products, though harmful to yeast at the strength at which they occur in autolysed yeast water, have no unfavourable influence on the lactic ferments even at the same strength.

The value of autolysed yeast water is due to a mixture of proteolytic products, the chief of which is peptone, and where small quantities of a series of substances, including leucine, asparagine and tyrosine, favour,

INDUSTRIES  
DEPENDING  
ON PLANTS  
PRODUCTS

independently of the yeast, the growth of the yeast and of the lactic bacteria.

The value of extract of malt is probably due to the presence of a series of proteolytic products similar to those in autolysed yeast (1).

**342 - The Milling and Baking Qualities of Australian Wheat.** — SCOTT, P. RANKIN and WINSLOW, F. G. B., in *The Journal of the Department of Agriculture of Victoria, Australia*, Vol. XV, Pt. 8, pp. 474-481, 1 diagr., 3 figs. Melbourne, August, 1917.

Wheat growing is one of the most important industries of Australia. New South Wales, South Australia, Western Australia and Victoria produce about  $4\frac{1}{2}$  times their own requirement in wheat. In order to control the wheat exported each year the Corn Section of the Chambers of Commerce of the four above-mentioned states fixes a standard of quality, called "fair average quality" or "F. A. Q. standard" which is representative of the quality of wheat produced each year. The standards fixed correspond to the quantity available, an average of 135 000 000 bushels, the yield from the separate States being: — Victoria, 50 000 000 bushels, South Australia, 40 000 000 bushels, New South Wales, 31 500 000 bushels, and Western Australia, 13 500 000 bushels (These totals do not include the quantities set aside for sowing and the feeding of poultry). The amount estimated for home consumption is 30 000 000 bushels, leaving, in normal years, 105 000 000 bushels for export, either as grain or as flour.

In order to ascertain the variations in quality due to climatic conditions during the period of growth experiments were carried out: — 1) to determine the amount of impurities and the proportion in which the various ingredients are present; 2) to classify the wheat according to size and determine the proportion of the various ingredients of each size; 3) to determine the unit weight per volume of original wheat and cleaned wheat; 4) the milling capacity; 5) to determine the gluten content, strength and colour of the flour; 6) its baking qualities.

The chief results are given in the appended tables. Table I shows that in one year, about 24 000 tons of impurities are exported mixed with the original wheat; if only cleaned wheat were exported the cost of shipping would be proportionately reduced; moreover, this quantity could be advantageously used in Australia for feeding cattle. The average percentages of impurities found in the wheats analysed during the four years 1912-13 to 1916-17 were: — New South Wales, 0.52; South Australia, 1.03, Western Australia, 0.59; Victoria, 1.01.

The measurements of the grain given in Table II are of importance in milling, where large, well-developed grain is preferred, as, the more uniform it is, the better does it mill. For most varieties, the larger the grain, the higher is the yield in flour. This does not always apply to a composite sample, as the bran layer is thicker in some varieties than in others. It would be very advantageous to sift the grain before exporting it, so as to

(1) As regards the use of artificial cultures of yeasts for making forage albumen, see *B*, November, 1915, No. 1201. (Ed.)

remove broken or shrivelled grain, the quantity of which was estimated at 12 408 tons, or 4.35 % of the yield, in 1916-17.

The results of the milling tests, given in Table III, show that the amount of water required to condition the wheat was greater than usual, the duration of the operation rather less. The wheats of South and Western Australia gave a high percentage of flour, those of New South Wales and Victoria, a low one. The colour of the flour of all the states was much below the average. None of these wheats can be considered of first quality as regards gluten content or water absorption capacity.

TABLE I. — *Amount (in grams) of foreign matter and unthreshed heads in Australian Wheat (1.000 grams taken).*

State	Barley	Chaff	Drake	Oats	Rubbish	Smut	Stem	Whiteheads	Wild Oats	Wild Seeds	Per cent.	Unthreshed heads per cent.
New South Wales .	0.48	1.52	0.05	0.56	0.52	0.12	0.07	0.19	0.48	0.14	0.413	2.04
South Australia .	2.41	1.47	2.34	0.36	0.84	0.79	0.38	0.38	0.14	0.14	0.925	0.62
Western Australia	2.67	1.73	1.46	0.31	0.34	0.09	0.06	1.29	0.06	0.04	0.805	0.40
Victoria . . . . .	1.79	2.98	2.23	1.84	0.48	0.22	0.28	0.61	0.33	0.27	1.103	1.59

TABLE II. — *Amount of grain (in grams retained on sieves of varying mesh (1000 grams taken).*

State	Size of mesh						Screenings under 2.00
	3.25	3.00	2.75	2.50	2.25	2.00	
New South Wales . .	9.5	75.5	122.5	407.0	224.0	107.0	54.0
South Australia . . .	13.5	263.5	280.5	333.0	65.5	14.0	30.0
Western Australia . .	5.0	198.5	325.5	358.5	74.0	17.5	21.0
Victoria . . . . .	4.0	162.0	199.0	442.5	118.5	45.5	28.0

TABLE III. — *Results of milling tests of F. A. Q. samples 1916-1917.*

State	Cleaned wheat Bushel weight lbs.	Dirty wheat Bushel weight lbs.	Break flour per cent.	Flour per cent.	Bran per cent.	Pollard per cent.	Colour 20 points max.	Strength quart water 200 lbs. flour	Wet gluten per cent.	Dry gluten per cent.	Moisture content Wheat per cent.	Moisture content Flour per cent.
Victoria . . . . .	64.7	60.25	7.5	69.2	17.2	12.6	15.5	17.0	19.25	7.11	11.70	13.06
South Australia . .	64.9	62.00	6.4	73.7	16.3	10.0	15.5	47.6	19.66	6.70	11.34	13.07
New South Wales .	60.9	56.75	5.4	68.6	21.0	10.4	14.5	44.3	18.82	7.00	11.53	13.06
Western Australia	67.1	62.75	3.6	74.9	17.4	7.7	17.0	49.9	22.9	8.01	10.38	12.30

The advantages to Australia of exporting flour instead of wheat are pointed out; they are a saving of  $\frac{1}{3}$  of the tonnage, the home use of the residue and by-products, the encouragement of the national industry.

343 - **The Soluble Nitrogenous Matter as an Index of the Baking Quality of Flour.** —

ROUSSEAU and SIROT, in *Comptes rendus des Séances de l'Académie des Sciences*, Vol. CLXVI, No. 4, pp. 190-192. Paris, January 28, 1918.

In 1913 the authors showed that, to an appreciable extent, it was possible to estimate the baking quality of flour by the ratio of the total nitrogen to the nitrogen soluble in water (1). They continued their study with different samples, considering the inverse ratio, which seemed preferable.

I. NORMAL FLOUR. — 1) *Flours of a bolting degree inferior to 70 %*. — The proportion of soluble nitrogen was about 17 % of the total nitrogen with a minimum of 16.1 % and a maximum of 19 %.

2) *Flours bolting over 70 %*. — The proportion of soluble nitrogen decreases as the bolting degree increases; proportions between 16.6 and 18.1 represent the best baking qualities.

3) *American flours*. — Many American flours very rich in gluten have a proportion of soluble nitrogen between 12.5 and 12.8 %. The addition of such flour improves native flours which "relâchent" (2), in which the ratio of soluble nitrogen to total nitrogen is very high; such addition lowers the ratio, making it almost normal.

II. ABNORMAL FLOUR (giving rise to difficulties in breadmaking). — The proportion of soluble nitrogen is above 20 %, more often about 22 %; it even rose to 62.5 % in a flour which had been stored a long time.

III. VARIOUS FLOURS. — The values found for the ratio soluble nitrogen: total nitrogen were: — maize, 18.1 and 18.5; rye, 22.7, 22.2 and 22.7; bean, 12.1; barley, about 12.1; rice, 4.27 and 4.20; one sample gave 2.5, another, although old, only 5.7.

The use of lime water in breadmaking (method of Messrs. LAPICQUE and LEGENDRE (3)) has a solvent action on the nitrogen and brings the proportion of soluble nitrogen of flours with a high bolting degree down to the normal.

The results may be summarised as follows: —

The presence of a certain percentage of soluble nitrogen in flour usually corresponds to a good absorption of water, and, consequently, to good kneading qualities of the dough, which is one of the most important qualities. The most advantageous proportion of soluble nitrogen to total nitrogen is about 16 to 17 %. If it rises or falls too much the flour will "relâche" and becomes of bad breadmaking quality. If the total nitrogen content is very high the flour is very hard to work.

The ratio of soluble nitrogen to total nitrogen, which is easily determined, can, therefore be of practical use in estimating the breadmaking qualities

(1) See B. May, 1913, No. 605. — (2) This term is applied to flour, usually made from badly harvested grain, which, after kneading, and when left for a time before being placed in baskets, gives out water which rises to the surface. The baker is obliged to add more flour and re-work the dough, thus obtaining less bread and a product of inferior quality. — (3) See R. Feb., 1918, No. 216. (Ed.).

of flour, not as an absolute criterion, but as a useful indication, especially when other analytical characters are lacking.

- 344 - **The Use of Chalk in Breadmaking.** — EFFTONT, JEAN, in the *Bulletin de la Société scientifique d'Hygiène alimentaire et d'alimentation rationnelle de l'homme*, Vol. V, No. 8, pp. 437-446. Paris, 1917.

In opposition to Messrs. LAPICQUE and LEGENDRE (1) who assert that the use of chalk inhibits the action of the soluble ferments contained in bran, which cause the acidification of bread, the author maintains that this acidity is not the result of enzyme action. The germinated grains may be treated with alkalis and acids in quantities 20 times higher than those at which enzymes in solution are destroyed without losing any of their active substances. Similarly, the soluble ferments of flour diluted in water\* can bear a temporary change in the reaction of the medium without any change occurring in the enzymes they contain. Sharps treated with chalk and then diluted in a mixture of flour and water keep all their active substances which, moreover, have no harmful effect on breadmaking.

The acidity of the flour, bad smell, bad keeping quality and the tendency of bread to go mouldy are not due to the enzymes of the bran, but to bacteria derived from insufficient cleaning of the grain and the presence of a large quantity of bran, the bacterial flora of which is richer than that of flour. The addition of 40 centigrams of chalk, as advocated in the new method, has no favourable action on the acidity, keeping qualities, or colour of the bread. In the presence of a fresh, strong yeast the amount of chalk advised has no action on the fermentation process. If the yeast is unsatisfactory, the introduction of chalk is certainly harmful.

Everything goes to prove that chalk bread is less easy to digest than ordinary bread, since the mono and tribasic phosphates, so favourable to salivary digestion, are replaced in the new bread by insoluble tribasic phosphates which have no influence on the very important first stage of digestion.

- 345 - **Tapioca Starch Made in Rhodesia.** — See No. 254 of this Review.

- 346 - **Copra Driers in Jamaica.** — WATES, L. A. in *The Journal of the Jamaica Agricultural Society*, Vol. XXI, No. 11, pp. 453-454. Kingston, Jamaica, November, 1917.

The increased production of copra in Jamaica has led to a large increase in the number of drying houses. During the last few years copra making has been carried out on a small scale on most estates, where, in nearly all the cases, it was dried on trays exposed to the sun. Today, practically every estate of any size has a drier. These driers are made on the model of that perfected by Mr. ED. ASHMAN at Boroughfield for drying cocoa. They consist of a practically air-tight wood or stone building, varying in size, containing a more or less large number of trays, heated by a furnace or stove, built in the wall, to which is attached a series of hot air pipes which

(1) See R. February, 1918, No. 216. (Ed.)

acts as a chimney or drought. A ventilator is let into the roof to regulate the heat.

Although all these driers are built more or less on the same lines, the details of their construction vary. Sometimes an ante-chamber, also practically air-tight, precedes the drying chamber. The trays are usually made of half-inch mesh wire on frames. The furnace of the best houses is so placed that the heating pipes start from about the level of the floor.

As a result of the different drying methods the quality of the copra produced also varies greatly, and often leaves much to be desired. The following technical points should be observed in drying the nuts and preparing the copra.

- 1) a white, pellucid copra, containing not more than 5 % moisture, should be aimed at ;
- 2) the split nuts should be exposed in the sun for half a day or so before use ;
- 3) the nuts should be kept in the drier at an initial temperature of from 160 to 170° F. for at least 12 hours ;
- 4) suitable ventilation for removing the moisture ;
- 5) final desiccation at 140° F.

A uniform distribution of the heat throughout the building, and constant and regular ventilation are essential to satisfactory drying. Since the hurricane of September, 1917, which blew down a large quantity of nuts, there has been great activity in making copra and further improvements are being made in the driers.

347 - **Wax from *Ceroxylon andicolum*.** — See No. 254 of this *Review*.

348 - **Note on the Fibre of *Wrightia annamensis*.** — CREVOST, C., in the *Bulletin économique de l'Indochine*, New Series, Year XX, pp. 48-491, figs. 2, plate 1. Hanoi-Haiphong, September-October, 1917.

*Wrightia annamensis* Eber. and Dub. (fam. Apocynaceae) occurs throughout Indochina; it is commonly called "Cay Long Muc" in Cochinchina, Annam and Tonkin, and "Chhœ u dâykhlâ" in Cambodia.

The author quotes the description by EBERHARD and DUBARD of this little tree whose wood resembles that of box. The fibres consist of hairs forming an umbrella round the seed. These hairs are lustrous, silky, wavy and slightly drooping; they are 3 or 4 cm. long, but there are much shorter hairs in the tuft; they taper slightly from the base towards the summit and have an average diameter of  $\frac{5}{100}$  to  $\frac{6}{100}$  mm. at the base, which is often reduced to  $\frac{1}{100}$  mm. at the summit. The wall is as much as 3 mm. thick, but it is usually 1.5 mm. They do not consist of pure cellulose, but of lignified cellulose.

Up to the present, all spinning tests have failed. The author boiled them in a lye to which soap was added (45 litres water, 230 gm. soap, 200 gm. Phenix lye). The product was turned slightly yellow by this bath, and unfortunately much of the natural lustre was lost. The mass of fibres thus treated and carded have the appearance of cottony down; the fibres

are tangled, waved, shrunk in places, and are suitable for spinning on the native wheel. The thread obtained from the spindle seems fairly well conditioned, but downy; spinning is rather delicate, and the thread is not so strong as cotton. Threads twisted together in 3, 4, or 5, gave strength like wool, and resemble soft wool to the touch. They easily dye with aniline colours. When knitted, a fabric is produced having a weight like that of wool, which it closely resembles. Weaving tests are to be undertaken.

The fibres of *Wrightia* might, on account of their cellulose, be used for making explosives.

The plant appears to occur over a large area in Indochina, and it seems to grow more quickly in southern than in northern regions.

## PLANT DISEASES

### DISEASES DUE TO FUNGI, BACTERIA AND OTHER LOWER PLANTS.

#### GENERAL

- 349 - **Parasitic Fungi Collected in the Government of Podolia, Russia** (1). — GARBOWSKI, L., in the *Bulletin trimestriel de la Société mycologique de France*,\* Vol. XXXIII, Pt. 3 and 4, pp. 73-91, figs. 1-4. Paris, 1918.

This is a list of 121 species of micromycetes living parasitically on cereals and other plants, both cultivated and wild, collected in 1915 in various districts of the government of Podolia. Four species are mentioned as being new to science, amongst them *Fusariella Populi*, found on leaves of *Populus tremula*, and *Macrosporium somniiferi*, on living leaves of *Papaver somniferum*.

- 350 - **Fungi of Southern China** (2). — YATES HARRY S., in *The Philippine Journal of Science* Section C, Botany, Vol. XII, No. 5, pp. 313-316. Manila, September, 1917.

This paper contains a list of fungi collected by Mr. E. D. MERRILL in Kwantung Province, in October and November, 1916. It includes: —

- 1) *Parodiella perisporioides* (B. and C.) Speng., on leaves of *Desmodium triflorum*, Canton (Honam Island);
- 2) *Trabutia chinense* n. sp., on leaves of *Ficus* sp., Loh Fau Mountain (Lofaushan);
- 3) *Phyllachora Coicis* P. Henn., on leaves of *Coix Lacryma-Jobi*, Canton;
- 4) *Phyll. Cynodontis* (Sacc.) Niessl., on leaves of *Cynodon Dactylon*, Canton;
- 5) *Phyll. orbicula* Rehm, on leaves of *Bambusa Blumeana*, Canton;
- 6) *Puccinia Cynodontis* Desm., on leaves of *Cynodon Dactylon*, Canton;
- 7) *Pucc. heterospora* B. and C., on leaves of *Prunus Persica*, Canton;
- 8) *Uredo cantonensis* n. sp., on leaves of *Melothria indica*, Canton;
- 9) *U. philippinensis* Syd., on leaves of *Cyperus* sp., Canton;
- 10) *Uromyces linearis* B. and Br., on leaves of *Panicum repens*, Canton;
- 11) *Ustilago Cynodontis* P. Henn., on inflorescences of *Cynodon Dactylon* Canton;

(1) See also R. Sept., 1917, No. 872. (Ed.)

(2) See also B. July, 1912, No. 1099; B. June, 1913, No. 754; B. June, 1914, No. 578. (Ed.)

12) *U. Koordersiana* Bref., on inflorescences of *Polygonum* sp. Canton ;

13) *Cercospora personata* (B. and C.) Ellis, on leaves of *Arachis hypogaea*, Canton ; this fungus is the cause of a serious disease of the peanut in the West Indies ; it has also been reported from the United States (1) and India, and is abundant on the leaves of Leguminosae in the Philippines ; it is very similar to, and may be identical with *Septogloeum Arachidis* Rac., which causes a serious disease of peanuts in Java and has also been reported from Ceylon ;

14) *Helminthosporium Ravenelii* Curt., on inflorescences of *Sporobolus elongatus*, Canton.

*Pseudomonas Citri* Hasse is also mentioned as living on leaves of *Citrus* sp. at Canton ; this bacterium, the cause of Citrus canker (2) was not found in the material examined, but the general appearance of the infected areas was that caused by this well-known microorganism.

MEANS  
OF PREVENTION  
AND CONTROL

358 - *Bacillus atrosepticus*, a Cause of "Blackleg" in Potato in Lancashire, England (3). — PAINE, SYDNEY, G. in *The Journal of Agricultural Science*, Vol. VIII, Pt. 4, pp. 480-494. Cambridge, 1917.

The damage done in Great Britain by potato bacteria is not so extensive as that done in other countries of Europe, the United States, and Canada. The loss caused probably does not exceed 5 % of the whole crop of Great

(1) See also R. May, 1916, No. 581, and R. May, 1917, No. 492. (Ed.) — (2) See also B. July, 1915, No. 763 and R. December, 1916, No. 1337. (Ed.) — (3) See B. Nov., 1910, p. 157. (Ed.)

DISEASES  
OF VARIOUS  
CROPS

Britain, but it may become more serious at any moment, as certain indications show.

Four or five different bacteria have been described in other countries as causing the disease of potatoes known as "Blackleg", but the cause in England has not yet been identified. The author undertook to determine which of the various microorganisms mentioned actually exist in Great Britain. For his research he used material collected in August, 1916 in the neighbourhood of Ormskirk (Lancashire).

The experiments lead to the conclusion that the bacterium causing Blackleg in Lancashire is *Bacillus atrosepcticus* (van Hall), which the author succeeded in isolating with great difficulty, and the morphological, cultural and physiological characters of which he describes in detail. Infection experiments gave positive results. This bacterium is in every way identical with that considered to cause the same disease in Ireland and described by PETHYBRIDGE and MURPHY under the name of *B. melanogenes*.

359 - Notes on Downy Mildew of the Vine in Australia. — CASTELLA, F. DE and BRITTLEBANK, C. C., in *The Journal of the Department of Agriculture of Victoria, Australia*, Vol. XV, Pt. II, pp. 685-700, figs. 1-2. Melbourne, November, 1917.

Till the summer of 1916-1917 Australian vineyards had not been attacked by downy mildew (*Plasmopara viticola*). The fungus had been reported, it is true, but only in an isolated case, on a private vineyard at South Yarra. The plant was uprooted and burnt and the disease was not again observed in Australia till January 31, 1917. Since then the fungus has appeared suddenly over wide areas of the north-east of Victoria.

As a rule the outbreak was slight. No damage was done and the fungus was not sufficiently in evidence, at least in any of the vineyards affected, to cause apprehension or to make spraying advisable. The origin of the 1917 outbreak is obscure, but there is no doubt that the excessive wetness of the summer was responsible for its development and spreading over so large an area.

It has been suggested, perhaps rightly so, that the grafted resistant rootlings imported from France during the last 10 years have acted as carriers. It is also possible that the fungus was introduced with dried grapes from Spain, Greece and Turkey. It is equally probable that the fungus existed in Victoria for a long time, but that, owing to climatic conditions, the white, downy efflorescence by which it is identified, was unable to manifest itself till the very wet summer of 1916-1917.

A description is given of the outward appearance of the disease, the damage it causes, the life history of the parasite and the methods of control used in Europe.

In normal summers Australian vine-growers, as those of California and the Cape, probably have little to fear from mildew, but the summer of 1917-1918 threatens to be even wetter than the preceding one. Spraying, when necessary, should prove much more efficacious in Australia than in France.

360 - Citrus Diseases in Surinam. — See No. 300 of this Review.

- 361 - *Blepharospora cambivora* n. gen. and n. sp., a Cause of "Ink Disease" in Chestnut Trees. — PETRI, L., in *Rendiconti delle sedute della R. Accademia dei Lincei, Classe di Scienze fisiche, matematiche e naturali*, Ser. 5, Vol. XXVI, Pt. 2. pp. 297-299. Rome, 1917.

In his last report on his investigations into "ink disease" of chestnut trees the author concluded that the causal parasite was a multicellular mycelium of intercellular and intracellular reproduction which remained unicellular for a more or less prolonged period, and formed in the cambium globular and threadlike haustoria. The mycelium, although grown on the most varied media, had always remained sterile (1).

Later investigations enabled the author to cause the formation of spores the characters of which place the parasite among the Saprolegniineae (Schröter) while bringing it near to the *Pythiaceae* and the *Peronosporaceae*. While waiting to give a fuller description later, the author calls this member of a new genus and a new species *Blepharospora cambivora*.

To produce the disease artificially the mycelium was inoculated into healthy chestnut trees at the "R. Istituto superiore forestale nazionale" at Florence. Isolated trees and those in plantations near infected centres in the province of Cuneo (Mondovì) were used. Of 13 chestnut trees from 5 to 6 years old, planted and inoculated on May 26, 1916, 9 were dead or dying about two months later. The characteristic brown spots of the collar rose towards the epigeal base of the stem and descended towards the most superficial roots. In trees about 60 years old the infection spread in six months from the cambium over about  $\frac{1}{8}$  of the whole circumference of the trunk.

In experiments carried out in Piedmont inoculations were made in August 1917, at the base of stems of young, strong shoots of chestnut trees of 10 to 15 years old in the Alma district of Frabosa Sottana (Mondovì). This district had not been attacked, but was next to a centre of infection. On October 2 some of the plants were examined and the infection was seen to have spread over almost half of the circumference of the stem, descending towards the collar. In some cases necrosis of the tissues was shown by a depression and brown coloration of the bark. The characters of the cambium and cortical tissues were identical with those of chestnut trees attacked by "ink disease".

- 362 - *Diaporthe taleola*, an Ascomycete Injurious to Oaks, in Switzerland. — MORELON, M., in the *Journal forestier suisse*, Year LXIX, No. 1, pp. 1-3, 1 plate. Berne, January, 1918.

During the second fortnight of September, under a slight wind, oaks (*Quercus pedunculata*, *Q. sessiliflora* and *Q. pubescens*) of 50 to 150 years old, isolated in coppices, on dry, calcareous soil, not very deep-rooted, to the south-west of the Vaudois Jura (Montcherand, at an altitude of about 1850 feet) lost several of their twigs. In some cases were counted ten branches per square yard, measuring as much as  $\frac{1}{2}$  inch in diameter and nearly 20 inches in length representing a premature loss of a maximum of 1% of the twigs of the tree.

(1) See R. Oct., 1917, No. 973, (Ed.)

An examination of these twigs showed their loss to be caused by *Diaporthe taleola* Fries. Similar damage was observed by the author in the copses of Corcelles-sur-Chavornay (1 900 feet), on clay, and at Sauvabelin, near Lausanne (2 030 feet), on molasse. Isolated oaks on the Zürichberg, above the town of Zurich, were also recently found to be attacked by the same fungus. This fungus had already been reported by Dr. VON TAVEL in 1903 on the Käferberg, near Zurich, and yet earlier (1893) R. HARTIG had drawn attention to the damage done by the ascomycete to oaks of about 35 years old in Germany and in Austria.

363 - *Chrysomyxa Abietis* in England and Scotland. — HILEY, W. E., in the *Quarterly Journal of Forestry*, Vol. XI, No. 3, pp. 191-192. London, July, 1917.

On May 15, 1917 in a small wood of mixed trees, south of Ridsdale, Northumberland, were found two spruces badly attacked by *Chrysomyxa Abietis* (Wallr.) Ung. The two trees were growing together and were badly stunted, but this could not be attributed to the fungus as only the leaves of the preceding year were attacked. One tree of normal size also had yellow patches caused by the fungus on some of its lower branches.

The presence of this fungus had not hitherto been reported in England; it was probably introduced from Scotland, where it has been frequently observed of recent years. The first report of the appearance of the parasite came from Aberdeenshire in 1911, where it was found on the estate of Durris, in the Dee valley. Later it was again observed in the same district, and, in 1916, was recorded from Perthshire.

Infection in England probably occurred in 1916, for, though the author could find no trace of the parasite on the 1915 shoots, the two above-mentioned trees were attacked on all the 1916 twigs except those at the top.

## WEEDS AND PARASITIC FLOWERING PLANTS

364 - Devil's Fig (*Solanum largiflorum*), a New Weed in Queensland. — WHITE, C. T. in the *Queensland Agricultural Journal*, Vol. VIII, Pt. 3, pp. 170-172. Brisbane, September, 1917.

This paper gives a botanical description of a new *Solanum* found up to the present in the Kin Kin district, Bundaberg and Childers, but doubtless growing in other districts as well. It has recently been reported as a great pest in the first of the three above-mentioned districts.

The plant was first considered to be a southern form of *S. Dallachii*, from which it differs in some respects. It does not seem to agree with any of the extra-Australian species. It is commonly called "Devil's Fig", but is also known as "Chinese Fig." This latter name is undesirable as the plant is native. The aboriginal name "Koori" of the old Bundaberg natives given under *Solanum Dallachii* by F. M. BAILEY (*Queensland Flora*, p. 1087) belongs to this new species.

If the weeds are few they may be grubbed out; repeated cutting off close to the ground exhausts the vitality of the plant, but this treatment

must be persistent to succeed; a little brine or caustic soda and arsenic about the cut surface is useful. Spraying with arsenical solutions does not seem of much value and is out of the question where cattle graze, but the injection of an arsenical solution into the main root or branch should prove successful.

365 - A Machine for Destroying Weeds. — See N.o 334 of this *Review*.

## INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

366 - Biological Observations on Some Insects in the Department of Hérault France. — PICARD, F., in the *Bulletin de la Société entomologique de France*, No. 19, pp. 355-357. Paris, 1917.

GENERAL

Special mention should be made of :

*Lixus iridis* Ol. — This curculionid, common on aquatic umbelliferae (*Helosciadium* = *Apium*, etc.), is sometimes injurious to celery near Montpellier.

*Pieris brassicae* L. — Among the parasites of the large white cabbage moth should be included the ichneumon *Pimpla alternans* Grav., which undergoes metamorphosis in the larvae of the macrolepidopteron. Three specimens reared by the author emerged November 30, 1917. It should be noted that this *Pimpla* does not develop in the larva but in the winter chrysalis of *Clysia ambiguella*.

*Pyrameis cardui* L. — The larva of this macrolepidopteron was reared on *Parietaria officinalis*.

*Charaxes jasius* L. — CH. OBERTHÜR doubts the presence of this lepidopteron in Languedoc. It is sometimes, though rarely, found in Hérault wherever the strawberry tree (*Arbustus Unedo*) grows. The author found larvae of the insect on specimens of Ericaceae at the School of Agriculture of Montpellier, and has been assured by all the lepidopteron collectors he has consulted that the adult insect has been taken in the gardens of the town and in several other localities.

*Carpocapsa pomonella* L. — This tortrix (apple pyralis) lives at Montpellier on the fruit of *Diospyros Kaki*, *D. Lotus* and other plants of the same genus. It did great damage to the crop in 1912 and 1913, a year in which the first generation of the microlepidopteron destroyed almost all the fruit.

*Agromyza abiens* Zett. — This dipteron was reported by P. MARCHAL as damaging artichokes near Perpignan. The author found it at Montpellier in the same plant under the same conditions. The larvae burrow in the leaves, along the veins, longitudinal galleries with very characteristic quadrangular expansions. There are many generations and damage is done in all seasons. The larvae were particularly numerous during the winter of 1913-1914; the exceptional cold of January, 1914, killed the greater part of them. Since then, the species, although it has not disappeared entirely, has become practically harmless.

*Scleroderma domesticum* Latr. — In the Montpellier Botanical Gardens

this proctotrupid hymenopteron is parasitic on the coleopteron *Phlaeosinus thuyae*, and the adult insect hibernates under the bark of cypress in galleries hollowed by the scolytid.

*Myrmecophila acervorum* Panz. — This myrmecophilous orthopteron is fairly common in the Department of Hérault. A long list of formicidae (genera *Camponotus*, *Formica*, *Lasius*, *Myrmica*, *Tetramorium*, *Solenopsis*) on which it may live has already been given. To the author's knowledge the gryllid has not yet been reported on members of the *Cremastogaster* genus. It is under bark, especially that of *Pinus halepensis*, in which is *Crem. scutellaris*, that this species of *Myrmecophila* is almost exclusively found, at least in Hérault. It is rarer under flat stones, where the author has found it with another formicid, *Pheidole pallidula*.

367 - Life History of *Macrosiphum illinoisensis*, the Grapevine Aphis. — BAKER, A. C., in the *Journal of Agricultural Research*, Vol. XI, No. 3, pp. 83-89, plates 8-9. Washington, October 15, 1917.

A short note on the alternation in food plants by this species was published in 1915 by BAKER and TURNER (1). The aphid was first described by SHIMER in 1866 under the name of *Aphis illinoisensis*. Later, in 1879, THOMAS described it as *Siphonophora viticola*, and it was always mentioned under the name of *viticola* Thos., until DAVIS, when listing the aphids of Illinois in 1910, drew attention to SHIMER's description and gave *viticola* Thos. as a synonym of *illinoisensis* Shimer.

The species is very abundant on wild grapes (*Vitis* spp.) in the more southern parts of the United States and often damages the cultivated varieties. Specimens of it have been collected in the District of Columbia, Georgia, Indiana, Maryland, Missouri, Mississippi, North Carolina, New Jersey, New York, Oklahoma, Pennsylvania, Texas and Virginia. An aphid which might belong to the same species was found on the vine at Campinas, Brazil, in September, 1898.

As there is no complete study in scientific literature of the different forms of the aphid the author considered it wise, in view of the economic importance of the insect, to record briefly the results of some of the most recent studies on it and to give a full description of the life history of the species.

368 - *Lepidium apetalum*, the Secondary Host of *Myzus cerasi* in Ontario, Canada. — ROSS, W. A. *The Canadian Entomologist*, Vol. XLIX, No. 12, p. 434. London, December, 1917.

Among entomologists there is a difference of opinion as to whether *Myzus cerasi* Fabr. (cherry aphid) is migratory. CROSBY considers the question undecided. SANDERSON and O'KANE state that, so far as is known, the aphid has only one food plant. GILLETTE states definitely that *M. cerasi* cannot change hosts. On the other hand, QUAINANCE and BAKER claim that the species is migratory.

(1) See B. Sept., 1915, No. 990. (Ed.)

The author's observations lead him to conclude that this aphid is partially monophagus and partially migratory. Apterous forms live throughout the season on the primary host — cherry — and alatae, born in summer, migrate and form colonies on a secondary host. In Ontario, according to the author's observations, the favourite secondary host is *Lepidium apetalum* (wild peppergrass). He collected several *M. cerasi* from this weed and succeeded repeatedly in transferring it from the cherry to peppergrass. There is no doubt that other crucifers serve as summer hosts. In insectary experiments the author successfully established colonies of *M. cerasi* on *Capsella Bursa-pastoris*, *Brassica arvensis* and *Erysimum cheiranthoides*, but the results have not yet been verified in the field.

- 369 — Sweet Sorghum Varieties Resistant to the Corn Earworm, in the United States.  
— See No. 279 of this Review.

RESISTANT  
PLANTS

- 370 — *Perezia mesnili* n. sp., a Protozoan Parasite of the Larvae of the Large White Cabbage Moth (*Pieris brassicae*), in France. — PAILLOT, A., in *Comptes rendus des séances de la Société de Biologie*, Vol. LXXXI, No. 2, pp. 66-68, 1 fig. Paris, 1918.

MEANS  
OF PREVENTION  
AND CONTROL

The paper describes a new microsporidium found in the larvae of *Pieris brassicae* collected in the Sathonay-Rillieux, Lyons, district. It attacks exclusively the Malpighian tubes and the silk glands of a fairly small percentage of the larvae of the macrolepidopteron. The author places this protozoan temporarily in the genus *Perezia*, but under the name of *P. mesnili* n. sp.

- 371 — *Hyperecteina polyphylla* n. sp., a Dipterous Parasite of the Injurious Coleopteron *Polyphylla fullo* in Russia. — VILLENEUVE, J., in *Bulletin de la Société entomologique de France*, No. 17, pp. 306-309. Paris, 1917.

Mr. Z. GOLOVIANKO, of Borispol (Russia) published at Kiev, in 1916, a study, printed in Russian and illustrated with many figures, on the development of two flies, one of which, in the larval stage, is saprophagous on a dead lamellicorn beetle, *Polyphylla fullo*; the other, parasitic on the same coleopteron, lays its eggs on the stomach of the living animal.

The author, taking as basis material sent to him by Mr. GOLOVIANKO, has ascertained the saprophagous dipterous, represented by two females, to belong to the genus *Sarcophaga*; this cannot be positively stated as there were no males.

The parasitic dipterous is an undescribed species which also exists in France; it belongs to the genus *Hyperecteina* and is closely allied to *H. metopina* Schiner, for which it has been mistaken. The author describes the insect under the name of *H. polyphyllae* n. sp. He possesses a male of this new species taken at Cape Breton (Landes) by Mr. J. DE GAULLE and has examined the two females sent by Mr. GOLOVIANKO.

- 372 — *Cosmopteryx phaeogastra* n. sp. and *C. bambusae* n. sp., Microlepidoptera attacking Beans and Bamboo respectively, in India. — MEYTRICK, E., in *The Entomologist's Monthly Magazine*, Vol. LIII (3rd. Ser., Vol. III), No. 642 (No. 35) pp. 257-258. London, November, 1917.

INSECTS, ETC.,  
INJURIOUS  
TO VARIOUS  
CROPS

This paper gives a morphological description of: —

1) *Cosmopteryx phaeogastra* n. sp., from larvae mining blotches in leaves of beans, at Pusa,

2) *C. Bambusae* n. sp., from larvae mining blotches in the leaves of bamboo, at Pusa.

373 - **Citrus Pests in Surinam.** — See No. 300 of this Review.

374 - ***Rhynchites baccus*, a Coleopteron Injurious to Apples, Apricots and Plums, in Sicily.** — DE STEFANI, T., in *Nuovi Annali di Agricoltura Siciliana*, Year VI, Ser. 6, Pt. 4, pp. 178-191. Palermo, 1917.

Repeated observations made by the author during a number of years shows that very serious damage is caused in the orchards of the mountains of Renda, in the Monreale district (province of Palermo), by the curculionid *Rhynchites bacchus*, and, to a much lesser degree by other insects of the same genus, such as *Rhynch. giganteus*, *Rhynch. auratus* and *Rhynch. ruber* (1).

*Rhynch. bacchus* attacks apricots and plums but especially apples. During many years the harvest was completely lost, and the author observed that the whole crop of apples and plums may be destroyed in about a week.

On apples and apricots the insect lays many eggs, but, according to the author's observations, only one on plums. Having laid its egg on the plum, the insect cuts the peduncle in about the middle, thus causing the fruit which is to feed the larva to fall to the ground. In apples and apricots, however, it either cuts the peduncle partly or not at all, so that the fruit dries up on the tree, falling only during wind or the autumn rains. Damp causes the fruit to soften and decompose, enabling the larvae within to enter the soil and complete their metamorphosis there.

All the insects do not lay eggs in good time. They do not, however, die during winter, but hide in a sheltered spot where they await spring, and the attack the fruit as soon as it has set. The author has found specimens of *Rhynch. bacchus* in November, December and January.

From many dried-up apples containing larvae of this coleopteron picked from trees by the author, emerged in September two parasitic hymenoptera, *Eupelmus degeeri* and a member of the genus *Syntomaspis*, which may form a new species. The former was present more frequently than the latter, but always in limited numbers, which leads the author to believe that these natural enemies are not really of importance.

The best methods of control are to collect the fallen fruit, each day at the same time in all infested orchards, and to pick that which is attacked but is still on the tree. The larvae in this fruit should then be killed. As a means of obtaining the desired result without total loss of the product, the author advises that the infested fruit be boiled and then given as food to pigs.

AGRICULTURAL INTELLIGENCE

GENERAL INFORMATION.

DEVELOPMENT  
OF  
AGRICULTURE  
IN DIFFERENT  
COUNTRIES

375 - **Agriculture in Crete.** — FRANCHET, L., in the *Revue Scientifique*, Year LVI, No. 3, pp. 75-81. Paris, February 2-9, 1918.

Crete is essentially an agricultural country, but cultivation there is still in a primitive state.

VINE GROWING. — Vine-growing, though remarkable in Crete, is much inferior to what it ought to be. The quality of the produce is entirely due to the exceptional climatic conditions and in no wise to the work of the growers. There are many varieties of grapes but the principal and only really appreciated ones are:—

*Black grapes*: — Cotzifalei, Mendillarei; Liatico.

*White grapes*: — Rasaccia, Croutakta, Sultanine.

The wine is of medium quality only, owing to inadequate methods of preparation, for it could be excellent. The best red wine is made from the Cotzifalei grapes. Wine made with Mendillarei grapes is less alcoholic than the former, whereas that made with Liatico grapes is more alcoholic; it is also less dark than that made with other red varieties.

Of the white grapes, Rasaccia is chiefly used as a dessert grape, and Croutakta for wine-making.

The Cretan wines would be excellent dessert wines, of the Marsala type. The production of wine is estimated at 2 970 000 imperial gallons; it could easily be increased tenfold. Certain wines have, on an average, 14 to 16°, but some occasionally are as high as 17°, and even 19°, according to the year.

Crete exports raisins, but in small quantities only. For this purpose the Croutakta variety is chiefly used, and prepared as follows: — the grapes are steeped for some hours in a solution of carbonate of soda, then left to

dry. They are generally sold only loose, the peduncle having been detached by the worker (women usually do this work) with her teeth. This method was the only one in use in Crete and Asia Minor till about 1910, but nowadays the peduncle is usually removed by machine. These raisins are exported and used in pastry-making, especially in Germany and Austria. The yellowish Sultanine variety, also known as "Corinthian", is also harvested. The peduncle is removed by machine and the raisins exported to Germany, Austria and Egypt.

The wine, residue and dried grapes are treated locally for the manufacture of alcohol, which is used in the country, the surplus being exported to the East. The annual production is from 352 000 to 396 000 gallons. The reddish alcohols, obtained by simple distillation, differ greatly in degrees, varying from 30 to 90°. The standard of the cognacs is from 38 to 45°.

Experiments on the manufacture of alcohol with locust-beans have not given satisfactory results.

**CEREALS.** — The cultivation of cereals is practically non-existent. The few natives and Turks who cultivate fields grow wheat and barley for their own use. The methods have remained unchanged for about 4 000 years. When the rich Messara plain is cultivated by modern methods it will yield sufficient wheat to supply the whole island with flour. At the present day about 12 000 metric tons of flour of different qualities are imported from Italy, Rumania and Bulgaria.

**OLIVE TREES.** — Olive trees, which grow with great ease in Crete, might prove one of the principal crops; in spite of the neglected condition of the trees they give an abundant yield. King George I made an attempt to improve the cultivation of olives by bringing specialists over from Italy to teach peasants the art of pruning. Unfortunately this experiment did not continue, and owners of olive orchards not only continue to neglect their tree, to the great detriment of the yield and quality of the fruit, but also to cut them for use as firewood, without considering the wealth they are gradually destroying.

The olives of Crete are of three qualities: — the psiloolies, small olives yielding a good oil, the chondroelies, large olives giving a less appreciated oil, and the tsounates, medium olives very rich in oil, but of which, unfortunately, there are only a few in the island. The harvest is from October to November.

When ripe the olives are not picked or knocked down with a pole, but left till they drop. Often they are not collected from the ground till partly rotten. The oil is extracted by crushing, but there are three factories which extract oil from the cake by the carbon bisulphide method. The yield is very variable, varying from 5 to 15 %.

The residue from the bisulphide treatment is thrown away, though, since it still contains 71 % of organic matter, it could be used as a fertiliser. A very small quantity of the olive oil is used for soap-making. The annual yield is about 5 500 000 lbs., only  $\frac{1}{7}$  of the yield about forty years

ago. This industry, in which primitive methods are still used, could develop largely if modern methods and material were employed.

**CITRONS.** — The citron, grown in the positions best exposed to the sun and sheltered from the north wind, yields abundantly. The fruit is gathered in August and December, and exported chiefly to the United States, England and Germany. Unfortunately the trees are subject to many diseases which do great damage, especially when the wood splits and the sap flows.

The fruit is not exported fresh, as it would not stand so long a journey, but is put in brine. It is cut into two or three, placed in barrels, and left to soak in sea-water with a large quantity of salt. It is left thus for several weeks, then taken out and sorted into two or three qualities. The pieces are then put back into the barrels, and well pressed. When the bottom of the barrel has been fixed, a hole is made in it and a new, very strong brine introduced. The barrel is then hermetically closed and is ready for export.

**TOBACCO.** — The climate, as well as the soil of Crete, are very favourable to tobacco growing. It was started seriously in 1899, and in 1901 the yield had risen from 33 000 lb. to 275 000 lb. When, however, the Greek Government took over the monopoly of tobacco, the native crop was completely ruined, and today only very medium tobacco imported from Greece or Turkey is used in the island.

The native tobacco itself is not good, but this is due solely to the method of preparing it; if well cultivated and well prepared, Cretan tobacco could rank with that of the best quality.

**VARIOUS FRUITS.** — Crete produces lemons, tangerines which are much appreciated, cherries, and apricots; the Japanese medlar does particularly well there. When the soil is treated by modern methods fruit production may become of considerable importance.

**STOCK BREEDING.** — Properly speaking stock breeding does not exist in Crete, and the flocks of sheep or goats belong to peasants who keep them for their own consumption, selling only the surplus. The rare oxen or cows are kept only as draught animals, for the Cretans do not like cows' milk and hardly drink goat's or sheep's milk. The little milk drunk in the towns is almost exclusively imported concentrated milk.

Goat and sheep's milk are used in the manufacture of inferior quality cheese, which turns rancid rapidly. The Cretans however, excel in the making of "yoghurt", curdled sheep's milk, a large quantity of which is consumed locally, and is also exported to Turkey and the coast of Asia Minor; Cretan yoghurt is famous in the East. Butter is not made, food being prepared with oil.

Cattle breeding could be successfully attempted, especially in the eastern part of the island, and should give very good results. If goats and sheep were bred rationally they might prove a source of great profit and permit the utilisation of the uncultivated mountainous parts of the island.

376 - **Agriculture and Forestry in Cyprus.** — MIDDLETON J. P., in *The Quarterly Review*, No. 451, pp. 401-423. London, 1917.

**AGRICULTURE.** — The cultivation of cereals on primitive lines is essentially the principal industry of the island; most of the land is held by the peasants as proprietors, but in some places the métayer system prevails. There are about 1 100 000 acres of cultivated land, and it is estimated that some 325 000 acres are still susceptible of cultivation.

A Department of Agriculture, staffed by a Director and other Assistants, including a veterinary surgeon, is endeavouring with some success to induce the farmers to adopt the use of manures and improved implements and systems. An experimental farm, started in 1903, was in 1907 converted into a stock and horse-breeding establishment, by means of which the general standard of stock and the native ponies have been much improved. The Government has also started ostrich breeding, an experiment so far not attended with quite the success anticipated. Cattle, horses, sheep, pigs and poultry, however, show, by their improvement in character and value, the wisdom of the Government efforts.

The cultivation of the vine, which extends over a large area, produces red and white wines of various types, forming one of the main staples of Cyprus trade. The application of sulphur to the vines has been made compulsory, and the extension of vine disease has thus been greatly lessened. The manufacture of wine is still generally primitive, but an English company, established for some twenty years, buys up the peasants' grapes and makes wine of a better character. Excellent brandy is also manufactured at Limassol. The value of wine exported in 1879 was £31 600; in 1880 it reached £46 000, rose to £53 685 in 1911, but fell again to £43 060 in 1913. These figures do not show any great increase in the output of wine, but there seems to have been a considerable extension in the production of raisins in later years, for whereas, in 1911 the value of raisins exported amounted to £29 636, it increased in 1913 to £39 002. This seems to show that it pays better to transform the splendid black grape of Cyprus into dried fruit than to manufacture wine.

Irrigation, as a Government undertaking has not apparently been attended with the success expected, partly owing to the thrifty habits of the peasants who wait for rain until the last moment; and partly owing to the evaporation consequent on summer storage. It appears that only some 600 acres of summer crop in the shape of cotton are grown. The peasants have their own rough methods of irrigation. There is no doubt that irrigation works wonders on the arid surface of the soil and amply repays its cost. Convinced of this the Government formed its first reservoir at Synkrasi; and others have since been completed. But the system of storage irrigation does not seem to commend itself to the villagers; and reclaimed lands attached to the reservoirs are but slowly taken up. In one of the reservoirs also the water has proved brackish and unsuitable for watering crops. The State only takes a "small fraction of the total increased production", while a considerable outlay is involved in paying compensation for land; the prospect of financial success is therefore uncertain at present.

Cyprus has suffered from the plague of locusts from time immemorial; and remedies for it engaged the attention of the English Government soon after the occupation. Each year the "screen and pit" method suggested by M. MATTER has been applied; and by means of this plan and by purchase of the eggs and the insects themselves at the suitable seasons the scourge was practically eradicated, but at a considerable expenditure, which was met by a Locust Tax. The surplus funds arising from this tax, which was in existence for some years, have afforded a convenient reservoir for unexpected emergencies. In later years, on a recrudescence of the plague, treatment by means of noxious chemicals has been tried, but met with objection from the peasants. A compromise has been effected under which this treatment is only applied to places where there is no risk to the animals of the villagers, while the old system of purchasing eggs and insects in their immature stage is resorted to elsewhere.

FORESTRY. — In ancient days Cyprus was no doubt rich in timber, and its mountain districts were clothed with trees varying with the altitude. In 1878, when Cyprus passed under British control, the condition of the so-called forests was deplorable, and it was clear that strong steps, aided by scientific knowledge and a Government Department, must at once be taken to remedy and stop the cause of destruction. An Ordinance was passed in 1879 for the delimitation and preservation of the forests; and successive Forest Officers sought to remedy some of the abuses by prosecution in the Courts, while the forest areas were gradually delimited and settled. They now extend to some 700 square miles.

The trees consist principally of the Aleppo pine, but, at an elevation of 4000 ft. and over, of *Pinus Laricio*. Large tracts are also covered with *Quercus alnifolia*, which is much in demand for making native ploughs and carts, while *Arbutus* flourishes in many places on the slopes of the hills and is used in the manufacture of rough furniture.

With very small sums voted annually to the Department, protection was the only course open to those in charge; and no progress in artificial reafforestation was made till many years after the occupation. Since 1907 special tree-planting has made considerable progress, some 300 miles of fire-paths have been made, and goats will gradually be excluded altogether by means of legislation passed in 1913 on the principle of local option for each village. The police protection has on the whole always been good, and there is no doubt that the forests of Cyprus are now in a fair way to recovery, and are likely to become an added source of beauty and prosperity to the island. It may be interesting to note in this connection that the rainfall appears of late years to have increased.

377 — A Biological Analysis of Pellagra-producing Diets. II. The Minimum Requirements of the Two Unidentified Dietary Factors for Maintenance as Contrasted with Growth (1). — McCOLLUM, E. V. and SIMMONS, N., in *The Journal of Biological Chemistry*, Vol. XXXII, No. 2, pp. 181-194 + 6 diagrams. Baltimore, Nov., 1917.

The authors draw attention to the fact that the previous experiments carried out at the Laboratory of Agricultural Chemistry of the University

RURAL  
HYGIENE

(1) For a review of the first part of this study see R. Jan., 1918, No. 2. (Ed.)

of Wisconsin, Madison, proved that of the four "deficiency diseases" — beri-beri or polyneuritis, scurvy, rickets and pellagra — caused, according to FUNK, by the absence of vitamins, only beri-beri can be called a "deficiency disease", in the sense the term is used by FUNK (*i. e.* caused especially by the deficiency of the water-soluble B), the other three being due to unsatisfactory relationships between the well recognised constituents of the normal diet. To polyneuritis must now be added another "deficiency disease", xerophthalmia, described in Japan by M. MORI (*Jahrbuch für Kinderheilkunde*, Vol. LIX, p. 175, 1904), in Denmark by G. E. BLOCH (*Ugeskrift for Læger*, Vol. LXXXIX, p. 349, 1917), and in Germany by A. CZERNY and A. KELLER (*Des Kindes*, Leipzig, 1906, Pt. 2, p. 67). This disease appears in children fed on a diet too rich in cereals and too poor in fats, and is manifest by emaciation accompanied by xerosis of the conjunctiva and keratomalacia, often ending in blindness. Experiments at the University of Wisconsin have shown that a diet deficient in the fat-soluble A causes, in animals, emaciation, oedema of the eyes, blindness and death. The animals may be cured, even when dying, by administering fats rich in the fat-soluble A (1), xerophthalmia being attributed to a lack of this factor in the composition of the diet.

The aim of the experiments described in this paper was to ascertain the quantity of each of the two unidentified dietary factors, A and B, necessary to the maintenance and growth of young rats. Wheat germ was chosen as source of the water-soluble B, and butter fat as that of the fat-soluble A. The diet was known to suffice for normal growth and prolonged maintenance of health when an adequate supply of both of the unidentified essentials was furnished. The diet consisted of: — casein 18.0, dextrin 76.3, salt mixture 3.7, agar-agar 2.0 %. It was fed: — *a*) with an abundance of fat-soluble A (as butter fat); *b*) with an abundance of water-soluble B (in wheat germ); *c*) with varying amounts, always below the optimum requirements, of both wheat germ and butter fat as sources of these two factors.

The results of the different experiments gave the following answers to the various questions raised: —

1) Assuming each of the food products, butter fat and wheat germ, to be of constant quality, what is the lowest intake of each which can supply enough of the A and B respectively just to prevent loss of weight? — The results show that a low plane of intake causes loss of vitality. When the minimum amount necessary to prevent loss of weight is approached, the life of the animal is endangered if the diet is persisted in.

2) When both essentials A and B are supplied in amounts just above the maintenance requirements will growth be proportional to these amounts,

(1) The fat-soluble A is found in fats of animal origin, such as the fats of butter and egg, and the fats extracted from internal organs (kidney, liver, etc.); it is abundant in leaves and in very few seeds (flax and millet); it is very scarce in animal body fats and absent in vegetable oils and fats. (*Journal of Biological Chemistry*, 1913, Vol. XV, p. 167; Vol. XVI, p. 423; *American Journal of Physiology*, Vol. XLI, p. 361, 1916 (*Author*).

or is a certain excess of each over this minimum necessary before growth in the young can take place? — The results show that, within certain limits, growth is proportional to the supply of the factors A and B in the diet, if all other factors are in proper proportion. For this reason the individual behaviour of the organisms to which these factors are administered cannot be eliminated.

3) Is the requirement of either A or B for maintenance or growth less when one of the two unknowns is present in liberal amounts, than when both are supplied in amounts near the minimum? — The experiments showed definitely that the animal can tolerate small quantities of A and B much better when the rest of the diet is well proportioned than when it is well constituted.

4) What is the effect on the health of animals of limiting them to a minimum supply of either the dietary A or B, the remaining one being supplied in abundance, or of limiting the supply of both to nearly the minimum requirement? — The life of the animals is undermined and endangered if the experimental conditions are such as to render growth impossible. The symptoms preceding the death of rats are similar to the characteristic symptoms of polyneuritis in pigeons.

378 — **The Biological Efficiency of Potato Nitrogen.** — ROSE, MARY S. and COOPER, IRENE F. (Department of Nutrition, Teachers College, Columbia University, New York), in *The Journal of Biological Chemistry*, Vol. XXX, No. 2, pp. 201-204. Baltimore, June, 1917.

A woman was submitted for 10 days to a diet of potatoes and clarified butter, which was sufficient for the total calorific energy. In this diet the potatoes supplied 0.1 % of the total nitrogen and nitrogen balance was maintained for 7 days (from the 4th to the 10th day of the experiment), with a total nitrogen intake of 0.096 gm. per kilo of live weight, equivalent to a net intake of 0.068 gm. per kilo of live weight. This result agrees with those of other workers, in which nitrogen equilibrium was maintained on potato nitrogen when the amount taken was from 0.04 to 0.08 gm. per kilo, and shows that the potato is a source of nitrogen of high food value, although only 63 % of the nitrogen is in the form of protein.

379 — **Food Value of Wholemeal and of 85 % Flour as Compared with White Flour.** — LAPICQUE, L. and CHAUSSIN, J., in *Comptes rendus des Séances de l'Académie des Sciences*, Vol. CLXVI, No. 7, pp. 300-302. Paris, February 18, 1918.

The authors carried out a series of systematic experiments to determine the value of 80 and 85 % flours.

1) — **FOOD VALUE OF WHOLEMEAL.** — The experiments showed the food value of wholemeal to be slightly greater than that of its weight of white flour minus the weight of the indigestible residue. Average wheat gives 12 % of such residue and its food value is equal to  $9^{80}/_{100}$  of its weight of white flour. The so-called work lost by the mastication, mixing and intestinal transport of this excess of inert substances causes no deduction in this case as the figures are based on the value for the maintenance of the organism.

2) — **COMPARATIVE VALUE OF WHITE BREAD AND BREAD MADE WITH**

85 % FLOUR (treated with lime water) (1). — The difference in value between the two breads studied was too slight to be seen. With a mixed diet this difference could not be detected.

If the changes which may arise through the acidity of the bread (2) are eliminated, and the differences caused by the formation of hydrates are avoided or compensated for, 85 % bread has practically the same food value as white bread.

380 - **Toxic Bread and Flour; Detection and Estimation of Sapotoxins.** — STOECKLIN, L., in *Annales des Falsifications et des Fraudes*, Year X, Nos. 109-110, pp. 561-572, 1 fig., 2 Diagrams. Paris, November-December, 1917.

The 85 % war bread has again raised the serious question of injurious flours made from uncleaned or badly cleaned wheat which contain a large proportion of foreign grains, some of them very toxic. A long time ago, when cow-wheat was a very common weed, there was in France an epidemic which was attributed to the presence of this grain in the bread. Now there are cases of another disease caused by corn-cockle, which, however, is harmful in a different way from cow-wheat. The presence of 4 gm. of corn-cockle, *i. e.*, about 200 mgm. of sapotoxins (toxic glucosides of the "saponin" type), may cause very marked disorders in adult human beings. Animals are, as a rule, much less sensitive to the effects of corn-cockle than man; it has no effect on sheep or rabbits, and may be used as a normal food for them, but 250 gm. of it will kill a calf (3).

Of all the foreign grains liable to become mixed with wheat, corn-cockle is the most dangerous, the more so because, by reason of its similarity to wheat in weight and size, it is difficult to eliminate. Public bodies made the seriousness of this danger known as soon as 85 % flour came into use, and, by a circular letter addressed to the Director of the Laboratories of Adulteration, and another to the agents of the Service for the Prevention of Fraud (dated August 17, 1917), the Minister of Agriculture gave instructions for distinguishing flour from badly cleaned wheat and the penalties to be imposed on those responsible. These instructions order to seek for and retain as:—

1) fraud, being not of the nature and quality demanded of the article sold (a fraud dealt with by Article 1 of the law of August 1, 1905), all flour containing an excess of foreign, but not dangerous, grains;

2) "injurious to health", with application of the regulations of Article 3 of the law of August 1, 1905 (which orders imprisonment for a period of 3 months to 2 years, independently of a fine of 500 to 10000 fr. (£20, to £397), flour containing impurities made up of dangerous grains the presence of which renders the flour toxic in the sense of the above-mentioned law.

It is easy to detect particles of corn-cockle in flour but a quantitative estimation is very difficult. The author based his method for the detection

(1) See R. Jan., 1918, No. 3, and Feb., 1918, No. 216. — (2) See R. March, 1918, No. 344. — (3) See also R., Nov. 1916, No. 1191. (Ed.)

and estimation of sapotoxins in flour on the capacity of the saponins to haemolyse red blood corpuscles (as in his research into the saponins of beer in 1911). His results were conclusive.

In toxicology the saponins are placed in the class of the so-called "haematic" poisons which act on the corpuscles and plasma. They are poisons of the circulation, especially of the heart and nerves, capable of causing irritation of the mucous membranes and serious digestive troubles. The sapotoxins haemolyse the blood, *i. e.* destroy the globules with formation of a red, perfectly clear and transparent liquid by the setting free and solution of the haemoglobin; it is an haemolysis caused by toxic injury.

The haemolytic reaction is specific for the detection of the sapotoxins of flour in an isotonic medium, *i. e.*, with a freezing point about  $0.56^{\circ}$  C. (most satisfactory in 0.95 % physiological salt serums), in very small quantities at ordinary temperature, using an emulsion of blood corpuscles freed from fibre and plasma (natural antihaemolysins), and avoiding all accidental causes of haemolysis (which may be controlled by making a test with a saponin-free flour).

REAGENTS. — Two reagents are required for the reaction : — 1) an artificial 0.95 % physiological serum ; 2) a 10 % blood emulsion (human blood, blood of oxen, sheep, horses or sheep) fulfilling the conditions given above.

METHOD : — I. DETECTION OF SAPOTOXINS IN FLOUR.

1) *Freeing the flour from fat* by extraction with dry ether.

2) *Extraction of sapotoxins* : — 1 hour in the hot-air oven at  $100^{\circ}$ , cooling, addition of physiological serum ; 1 hour at  $40-45^{\circ}$  with frequent shaking ;  $\frac{3}{4}$  hour in the centrifuge ; filtration.

3) *Haemolytic reaction* : — the blood reagent is added to the extract obtained ; if the liquid becomes transparent sapotoxin is present ; the duration of the reaction varies from a few seconds to several hours, the more sapotoxin there is present, the shorter it is.

II. QUANTITATIVE DETERMINATION : — The rate of haemolysis is dependent on : — 1) the concentration of the sapotoxins ; 2) the temperature of the reaction ; 3) the nature of the blood ; 4) the age and concentration of the blood emulsion. There is a mathematical relation, which may be expressed by a regular curve, between the speed and concentration, all other conditions being equal. The author has drawn up diagrams giving an idea of speed in relation to concentration which are often sufficiently approximate for practical use ; nevertheless, for an exact analysis, it is best for the worker to compare the types and draw his own curve.

381 — **The Prevention of Malta Fever by Active Immunisation of Animal Carriers.** — VINCENT, H., in *Comptes rendus des Séances de l'Académie des Sciences*, Vol. CLXVI, No. 8, pp. 359-362. Paris, February 25, 1918.

Malta fever, caused by *Micrococcus melitensis*, originally considered to be restricted to Malta and Gibraltar, is in reality found in many countries, particularly those bordering on the Mediterranean.

The animal which is most subject to this disease and most capable of transmitting it to man is the goat. There is every reason to believe that the active immunisation of the goat by *M. melitensis* is possible. As a

rule this animal only shows slight morbid symptoms, although it harbours the pathogenic organism for a long period. On the other hand, it may recover spontaneously from the disease after a variable period and, when recovered is immune. The author attempted to increase this natural resistance by vaccination with different strains of *M. melitensis*.

It is impossible to immunise the animals with a living virus, as that would cause infection amongst them; they must be vaccinated with a dead virus. The author prepared a polyvalent vaccine (gelatine cultures, 3 or 4 days old, diluted in physiological water, sterilised by shaking with ether and contact with it for 2 hours) with 10 strains of *M. melitensis* and one of *M. paramelitensis*. The vaccine contained about two thousand million micrococci per cc. Two injections of 2 cc. each were made at intervals of 5 or 8 days. A description is given of the experiments.

More than 200 young and adult goats were vaccinated; they included: —1) adult goats and he-goats; 2) kids 2 to 3 months old; 3) goats pregnant since 1 to 3 months; 4) goats in milk. No special symptoms were noted. After a few hours the injections caused a rise in temperature of 0.5 to 1°C.; the following day the temperature was normal. The goats kept their appetite. Those in kid suffered no bad effects, and pregnancy was not influenced by the injections.

This method of immunising goats and other animals capable of transmitting Malta fever by their milk or excreta or by direct contagion, may have the double effect of protecting these animals and, indirectly, man himself, against this serious disease.

382 — **Loss of Power of Infection of Marsh Anopheles during Hibernation.** — ROUBAUD, E., in *Comptes-rendus des Séances de l'Académie des Sciences*, Vol. CLXVI, No. 6, pp. 264-266. Paris, February 11, 1918.

Recent experiments have shown that not only do the salivary glands of marsh anopheles lose their sporozoites after a relatively small number of punctures, but that the sporozoites, if they have not been ejected, slowly degenerate in the tissues of the glands or the saliva. A prolonged conservation of the power of infection in infected anopheles does not seem possible. Unlike trypanosomic infection by *Glossina*, which generally lasts till the death of the infected fly, the salivary plasmodic infection of anopheles is only temporary. The saliva of mosquitos cannot, thus, be considered as an hibernation medium of malarial sporozoites.

EXPERIMENTAL  
AND  
ANALYTICAL  
WORK

383 — **Electric Farming in the United States.** — MOULTON, ROBERT H., in *Hoard's Dairyman*, Vol. LIV, No. 23, pp. 797 and 816, 3 figs. Fort Atkinson, Wis., December 28, 1917.

Experiments on electric farming (1) were made under the direction of Dr. HERBERT G. DORSEY and Mr. F. M. TAIT near Dayton, Ohio (Miami River Valley).

In the preliminary tests small plots were subjected to different kinds of electrification. To prevent the soil of one plot from being better than that of another, top earth was collected, mixed, sifted and then laid to the

(1) As regards Electric Farming, see R, Jan, 1918, No. 10 (Ed).

uniform depth of 7 inches over the whole area. In plot No. 1 was buried a wire screen, a wire network was stretched about 15 inches from the ground, and both connected by several wire antennae. The screen was connected to one terminal of a Tesla coil, and the network to the other. A transformer supplied an alternating current of from 110 to 5000 volts, charging a condenser of tinfoil and glass plate, which discharged through a primary of the coil. About 130 watts were supplied for an hour each morning and evening.

Plot No. 2 was lit by a 100 watt tungsten lamp with a ruby bulb for 3 hours daily, beginning from sunset. Plot No. 3 was lit in a similar way, but with a mercury vapour lamp. Plot No. 4 was untreated and served as control. In plot No. 5 was buried a wire network connected to the terminal of a 110-volt direct current. The positive terminal was attached to a small sprinkling can with a carbon electrode in its centre. The can was filled, the water electrolysed for several minutes, and the plot sprinkled with the water from the can, the theory being that the current should penetrate the soil in the water. Plots Nos. 6 and 7 were subdivided into four plots each 2 ft. square, separated by porcelain insulators and arranged with carbon electrodes at each end. Both direct and alternating currents were applied to these electrodes. Radishes and lettuce were sown and, when germination had begun, the different methods of electrification were tested with great care.

The plants in plot No. 1 grew much more rapidly than those of the other plots and weighed more than double those of the control bed. This convinced the experimenters that electrification of the ground by high-frequency currents stimulated plant life to an extent which justified a more complete investigation. Two acres of flat, rich ground were, consequently, selected for further tests.

Fifteen feet above the ground was built a network of sprinkling pipes, which ran east to west for a distance of 200 feet, the pipes being 50 feet apart. In the north-east corner, from north to south, were stretched 7 copper wires, each 200 feet long, at intervals of 15 feet. The wires were placed high enough for the soil to be ploughed with horses. The ends of the wire were attached to insulators on the top of gas pipes set in concrete. A small transformer house was built at the eastern end of the house and machinery capable of supplying 10 000 volts installed. A choke coil and a Tesla coil were used. The whole was so connected that the current from the wire network was sent by the antennae to the network of sprinkling pipes, which were adequately connected with the ground. Towards the end of July the system was ready and the currents tested. At that time a pressure of 50 000 volts was obtained and the frequency of the alternating currents was estimated at 30 000 cycles a second. Birds alighting on the wires were stunned and thrown to the ground, but none were killed. The ground was planted with radishes, lettuce, beet, cabbage, cucumbers, turnips, musk-melons, water-melons, parsnips, beans, peas, maize, and tobacco. All were planted in rows running from east to west, so that one half of each row was electrified and the other half not.

Practically all the plants in the electrified area grew more rapidly than those out of it. In nearly every case the electrified plants ripened a fortnight earlier than the untreated ones. The tobacco plants from the electrified area weighed, on the average, 1687 gm.; those of the unelectrified area, harvested two weeks later, only weighed 1632 gm. each. Considering that the tobacco plant grows most rapidly in the two weeks preceding ripening, it was estimated that the actual increase in weight of the plants in the electrified zone was 20 % more than that in the unelectrified zone.

Before electricity can be applied practically for stimulating plant growth many problems must be solved which are now being investigated in greenhouses in all parts of the United States. (The author draws attention to the experiments made by English workers who attempted to stimulate animal life by electricity. Two large incubators containing newly hatched chickens were taken, one being subjected to high-frequency currents, the other being used as a control. The chickens in the first incubator grew much more rapidly than the others).

Mr. W STAHL, an electrician, used electricity on plants on one of his farms near Chicago. A network of wires, from 10 to 20 feet apart, was placed in the earth at a depth of about 1 ½ feet; above the ground was another network of wires about 1 foot apart. Twice a day, morning and evening, the electric current was turned on from the main switch-board. The power was supplied by the city electric light plant, and the cost for the period necessary to ripen a crop was \$ 2.50 to \$ 4.00 per acre. The electric treatment was started just when the plant began to come out of the ground and continued till the crops were about ready to be harvested. The cost of installation is repaid by the increase in crops, and the cost of the current is more than compensated for by the saving in the cost of labour, and the more rapid growth and harvesting of the crop.

In 1917, Mr. STAHL gave a demonstration of the electric treatment of plants on a two-acre plot of his farm. He grew beans, tomatoes, beets, melons and other vegetables, which ripened much earlier than those on neighbouring farms, and allowed a second crop to be ripened before winter. The electrified plants are distinguished by their excellent quality.

## CROPS AND CULTIVATION

AGRICULTURAL  
METEOROLOGY

384 - Effect of Meteorological Factors on the Maturation of the Tissues and the Resistance to Cold of the Vine in U. S. A. — GLADWIN, F. E., *New in York Agricultural Experiment Station, Bulletin No. 433*, pp. 107-139. New York, April, 1917.

During the spring of 1916 Concord vines, at Fredonia, Kentucky, suffered severely from frost; a large proportion of the buds were killed, and many of the shoots dried up later.

An examination of the effects of meteorological factors on the growth of the vine, seemed to prove that the real cause of the damage is not the low temperature of spring, but rather the climatic conditions of the previous year, which prevent both the buds and the wood from maturing completely

before winter ; this may be seen from the low water content of the tissues and the thickening of the cell walls.

Abundant rain and high temperature up till the beginning of October followed by a sudden drop in temperature, are conditions favourable to good development of the tissues, which continue to produce thin-walled, turgescient cells, until the sudden cold stops growth and brings about the winter stage before the buds and wood are mature. It is rare that all the buds mature completely ; generally the first 5 or 6 on the base of the cane, and those near the apex are incompletely mature, and are clearly the most sensitive to adverse weather conditions, in winter and especially at the beginning of spring, *i. e.* when growth re-starts.

Maturity of the wood and buds is probably correlated with the ripeness of the fruit as measured by the sugar content of the juice. The meteorological conditions which determine complete ripening of the fruit also determine ripening of the fruit and buds. The 1914 crop was above the average, the grapes ripened completely, so did the plant tissues, as is shown by the low number of buds destroyed by the spring frosts. If the meteorological data of 1914 are compared with those of the year 1915-1916, two factors are seen :—

1) In 1915, many clouds, abundant rain and large number of wet days in August, September and October retarded evaporation, so that the soil was continually wet.

2) In 1915, September was much warmer than in 1914, a difference of 3.2° F. in the average daily temperature. The moisture of the soil and the warmth favoured late growth of the wood and retarded its ripening as well as that of the fruit.

3) In 1916, a high percentage of buds was destroyed in some varieties, whereas in others they were totally destroyed. The damage was not limited to certain districts but spread over the whole grape-belt. The abnormal warmth towards the end of January and the March frost alone would certainly not have had such disastrous effects if the incomplete maturity of the wood and the buds had not decreased the resistance of the plants to cold.

According to experiments made by the author, various types of fertilisers, nitrogenous, phosphatic and potassic, have no influence on maturity, and cannot, therefore, lessen the effect of low temperature.

To estimate the damage suffered during the season winter-spring 1916, 146 different vines were examined and the percentage of buds destroyed on each was calculated. All the plants were not damaged to the same extent and they could be divided into 3 groups as follows :

GROUP I. — *Least damaged vines* : 10 to 20 % of the buds destroyed : Mission, 10 % — Noah, 12 % — Cottage, 13 % — Moor Diamond, Hubbard, 14 % — Aroma, Dracut Amber, Woodruff, 15 % — Little Wonder, 16 % — Barry, 17 % — Concord, 18 % — Pocklington and Beta, 19 % — Martha, No. 264, 20 %.

GROUP II. — *Most damaged vines* : 80 to 100 % of the buds destroyed : Empire State and Dewdrop, 80 % — Brighton and Ontario, 82 % — Green Ea, 83 % — Diana, 86 % — Secretary, 88 % — Station No. 939, Dod Ridge, *Vitis Berlandieri*, 90 % — Ulster and Eu-

model, 92 % — Delakins and Dutchess, 94 % — Isabella, 95 % — Captivator, 96 % — Lady Washington, Armalaga, Westfield, No 3 516 : 99 % — Herbemont, Mills, Black Eagle, Rebecca, Nos 267 and 268, 100 %

GROUP III — *All the other vines examined* : 21 to 79 % of the buds destroyed.

To what is the difference in susceptibility of the various vines due ? First of all, it is seen that different varieties of the same species in no wise show the same degree of resistance. In the *Labrusca* varieties the damage varies from 13 % for the Cottage variety, to 78 % for Wyoming, the *Riparia* varieties vary from 12 % for Noah, to 88 % for Secretary, the *Aestivalis* varieties from 22 % for Wine King to 94 % for Dutchess. As a whole the *Aestivalis* group is more susceptible than the *Riparia* group or the *Labrusca* group, which is the most resistant. The *Labrusca* × *Vinifera* hybrids vary from 15 % for Woodruff to 100 % for Mills and Rebecca, the degree of resistance increasing in proportion as the characters of *Labrusca* predominate. It has been proved that, in New York State, the *Vinifera* varieties cannot survive the winter. Pure *Riparia* varieties have proved fairly resistant (Gloire, 29 % and Grand Feuilles 21 % of damage), and so have the *Rupestris* varieties (St. George, 29 % ; Mission, 10 %)

The above data shows clearly that certain species, as well as certain varieties of the same species, are more resistant than others, and capable of ripening their wood and buds more rapidly. The texture of the wood varies in different species and varieties of vine, but, so far, there have been no investigations into the possible correlation of wood hardness and resistance to cold.

385 — **Vegetation as an Indicator of the Fertility of Sandy Pine Plains Soils in Northern Wisconsin.** — DUNNEWALD, T J, in the *Journal of the American Society of Agronomy*, Vol. X, No 1 pp. 19-23, 5 tables, 1 diagram Lancaster, Pa., January 20, 1918.

While making a survey of part of northern Wisconsin it was noticed that the soils of sandy plains varied considerably in their ability to produce a second growth after the removal of the pines and the many severe fires which succeeded logging operations.

The most sandy portions, where the original timber was sparse, or consisted chiefly of Norway pine (*Pinus resinosa*) and Jack pine (*P. Banksiana*), with, perhaps a few white pines (*P. Strobus*), now bear little or no second growth. Small Jack or Norway pines, 6 to 10 ft. high, appear in clumps, and the poplar brush, if any, is also less than 10 ft. high, while a thick growth of sweetfern (*Myrrhis odorata*), bracken (*Pteris aquilina*), blueberries (*Vaccinium corymbosum*), or coarse bunch grass (*Elymus* sp.), is the only ground cover. In other places, where the moisture conditions appear somewhat better and the soil slightly more loamy, the second growth is often 20 to 40 ft. high, and consists of poplars, white birch, cherry, alder, and young white pine, with but few Jack or Norway pines. The original timber here had also been of better quality, mostly large white and Norway pines.

In this botanical examination of soils on the basis of their value for agricultural purposes, the most sandy soil was considered to be of low

value for farming, while the more loamy soil (indicated by the vegetation and better moisture conditions) was classed as fairly good. Typical samples were taken from widely-separated areas of these two soils, and mechanical and chemical analyses made. The results show that the soils with a small or sparse second growth should be classed as coarse or medium sand, whereas those with strong second growth should be classed as fine sand. The second type contains about the same amount of fine clay as the first, but much more silt and, particularly, much more fine sand. The averages of the principal fertilising elements in the different soils are given below: —

	Coarse sands			Loamy and fine sands		
	Phosphorus %	Potassium %	Nitrogen %	Phosphorus %	Potassium %	Nitrogen %
Soil (top 8 inches) . . .	0.048	1.12	0.071	0.055	1.05	0.081
Subsoil . . . . .	0.032	1.06	0.037	0.037	1.13	0.035

The coarse sandy soils contain 0.82 % calcium, the loamy and fine sandy soils 1.16 %. It is seen that the greatest difference in the food elements of the soil of the two groups is in the phosphorus; both the types are poorer than other classes of soil containing finer material (clay and silt).

The moisture equivalent (determined by letting each sample absorb as much water as it will hold, then subjecting it to centrifugalisation at 2 440 revolutions per minute for 40 minutes, and determining the percentage of moisture after treatment) was: — *coarse sands*: — soil, 14.92; subsoil, 9.48; *loamy and fine sands*: — soil, 19.40, subsoil, 13.76; *i. e.* the fine sands exceed the coarse ones by about  $\frac{1}{3}$  (27 %) for this important factor.

In conclusion it may be said that the undergrowth of cleared woodland is a good indication of the cropping capacity of the soil; heavier growth shows a higher content of plant food, the presence of more fine material in the soil, and especially a greater moisture-retaining capacity, enabling the vegetation to resist drought.

386 — **The Growth of Sheep Sorrel (*Rumex Acetosella*) in Calcareous and Dolomitic Media, in the United States.** — MACINTYRE, W. H., in the *Journal of the American Society of Agronomy*, Vol. X, No. 1, pp. 29-31, 1 plate. Lancaster, Pa., January 20, 1918.

The work described was carried out at the Agricultural Experiment Station of the University of Tennessee, by Dr. J. I. HARDY, under the direction of the author.

In 10 pots was placed a mixture of clean sand and limestone (92 %  $\text{CaCO}_3$ ), and in 10 others a mixture of sand and dolomite (about 50 %  $\text{CaCO}_3$  and 35 %  $\text{MgCO}_3$ ). The percentages of limestone and dolomite used were 100, 75, 50, 25, 15, 5, 2.5, 1, 0.5, 0. Eight stolons of equal size were placed in each pot with lime on June 13, and harvested, with their roots, on September 22, 1913 (101 days of growth), and in each pot with dolomite on March 31, and harvested July 8, 1914 (99 days of growth). The results, given in the appended table, show that sorrel (usually considered to indicate

a lack of lime in the soil) can grow well in a strongly alkaline soil. The photographs which accompany the paper show that the roots developed vigorously even in the presence of considerable quantities of limestone and dolomite.

*Weight in grams of whole air-dried sorrel plants, grown in pots containing varying percentages of limestone and dolomite.*

	Pot number									
	1	2	3	4	5	6	7	8	9	10
Sand + limestone. . . . .	1.61	0.42	1.06	1.91	0.75	1.83	1.48	1.24	0.51	1.82
Sand + dolomite . . . . .	3.34	6.54	1.20	1.51	1.38	1.02	1.57	3.96	3.87	1.60

387 - **Movement of Soluble Salts Through Soils** (1). — MC COOL, M. M. (Professor of Soils) and WHEETING, L. C. (Instructor in Soils, Michigan Agricultural Experiment Station), in the *Journal of Agricultural Research*, Vol. XI, No. 11, pp. 531-547, 16 Tables, 5 Figs. Washington, December, 1917.

The principal work on this subject is first reviewed :—

1) MUNTZ and GAUDECHON concluded that, in rather dry soils, certain fertilizer salts take up water from the surrounding soil and remain for a long time localized in the moist area ; in somewhat moist soils this movement does not take place, and, even in moist soils, the diffusion of the salts is very slow on account of the discontinuity of the soil mass.

2) MALPRAUX and LEFORT, who studied the movement of nitrates in sandy and loam soil respectively showed that, both horizontally and vertically, the salts diffuse very slowly.

3) DEMOLON and BROUET showed that salts have a general tendency to remain at the surface of the soil and that rather large amounts of rain are required to carry nitrates into the subsoil.

The authors then describe the new experiments they carried out to control the results hitherto obtained ; one series was made with fine-textured soils, and a second with coarse textured soils. Their principal results may be summarised as follows :—

1) In moist soils the soluble salts move from regions of high to those of lower concentration. The movement is rather rapid and the salts do not remain long localized as has been stated by previous workers. Moreover, the water content of the soil and the amount of salt present influence the rate of movement.

2) Where moisture is lost by evaporation the upward movement is more rapid than the downward movement in heavy soils ; in coarser soils, such as sand, the downward movement is slight. This explains why, during drought, the soluble salts are more exposed to loss by upward movement in sandy soils than in heavier soils.

3) Chemical analyses show that, as the salts move through the soil,

(1) See also R. 1916, No. 615. (Ed)

the solution in the various layers of soil changes in composition. These changes vary according to the physical nature of the soil. Thus, the addition of 1 % of sodium chloride caused, in the soil solution of sandy soil, a gradual increase in the calcium and magnesium content in the layers above that to which the chloride was added. In silt loam, however, the maximum magnesium and calcium content were in the second layer, and dropped sharply in the third and fourth layers. These changes in composition should have an important influence on the effects produced by the use of fertilizer salts.

4) The movement of soluble salts in the soils is brought about by diffusion as a result of the chemical reaction in the soil and by the movement of the water (1).

388 - **Total Nitrogen and Carbon (2) in Cultivated Land and Land Abandoned to Grass and Weeds.** — BLAIR, A. W. and MC LEAN, H. G. (New Jersey Agricultural Experiment Station), in *Soil Science*, Vol. IV, No. 4, pp. 283-293, 1 Fig., bibliography of 18 publications. Baltimore, October, 1917.

The work already done on this subject proves beyond doubt that the nitrogen and organic matter of cultivated land are rapidly exhausted in spite of the addition of fertilisers and green manures. In uncultivated land, however, the loss is less, and, in some cases, there are pronounced gains. Although the loss of nitrogen in cultivated land is partly due to the crops, which absorb a certain quantity of it, and to drainage waters in which it occurs as nitrates, the information available is not very definite.

In 1913 and 1916 the authors determined the nitrogen content of a sandy-loam soil allowed to run wild from 1908 to 1916, receiving annually during that period 600 lbs. of dried fish manure per acre. The nitrogen content remained fairly constant, but the carbon content increased slightly from 1913 to 1916.

On the other hand, the average nitrogen content of adjoining crops under a five year rotation (maize, oats, wheat, two years of grass) was 0.02 % less in 1913 and 0.023 % less in 1916 than that of the corresponding uncultivated plots, and the carbon content 0.27 % less in 1913 and 0.30 % less in 1916.

Two cultivated plots which received no nitrogen and were used as controls, gave an average total of 196.13 lbs. of nitrogen in their crops during the nine years. From six plots treated with nitrogenous manure during the same period, an average of 329.94 lbs of the organic nitrogen applied was recovered.

It is thus clear that the percentage of nitrogen and carbon in cultivated soils decreases even when 600 lbs. per acre of dried fish manure are applied annually, whereas the percentage of nitrogen in uncultivated soils which have received the same organic nitrogenous fertiliser remains about constant. The experiments show that, in cultivated soils, nitrogen is the limiting factor, and the fact that nearly  $\frac{2}{3}$  of the nitrogen of organic nitro-

(1) Other work in the United States on the concentration of nitrates in the soil confirm these conclusions. See R. Feb., 1918, No. 129. — (2) See R., Jan., 1918, No. 8. (Ed.)

genous fertilisers is unaccounted for is not in favour of the use of commercial nitrogenous fertilisers of an organic nature if those of mineral origin are available.

- 389 - **The Effect of Different Salts on Ammonia Formation in Soil.** — KOCH, G. P. (New Jersey Agricultural College Experiment Station, New Brunswick), in *The Journal of Biological Chemistry*, Vol. XXXI, No. 2, pp. 411-413, bibliography of 5 publications. Baltimore, August, 1917.

It has been shown by TOTTINGHAM and SHIVE, using plants in nutrient solutions of controlled concentrations, that high concentrations of salts are injurious to plants, while the same combination of salts at lower concentrations does not retard their growth. Similarly, the writer, controlling the concentration of the solution, studied the effects of a 3-salt solution (the physiological balance in nutrient solution) upon the decomposition of dialysed peptone by a pure culture of bacteria and found the same effects. So, in order to avoid osmotic differences all solutions used in the work were made up to an osmotic pressure of 2 atmospheres.

Different combinations of magnesium sulphate, potassium sulphate and monocalcium phosphate were applied to 100 gm. of soil mixed with 155 mgm. of nitrogen (dried blood). The mixture was incubated for 8 days and the ammonia distilled off by the usual method.

The following results were obtained:

1) In combinations of the salts where monocalcium phosphate was present in only 0.1 of the total concentration, a considerable increase in ammonia formation was apparent.

2) When 0.8, 0.9, or all of the total concentration was supplied by monocalcium phosphate, the ammonia formation was approximately 26.0 % greater than when no salts were added to the soil.

3) Magnesium sulphate and potassium sulphate singly or in combination were toxic where no monocalcium phosphate was added to the combination.

- 390 - **Aluminium as a Factor Influencing the Effect of Acid Soils on Different Crops.** — HARTWELL, BURT L. and PEMBER, F. R., in the *Journal of the American Society of Agronomy*, Vol. X, No. 1, pp. 45-47. Lancaster, Pa., January 20, 1918.

Many workers have called attention to the injurious effects of the hydrolysis of aluminium salts, caused by the liberation of free acids, measured by an increase in the hydrogen-ion concentration. Hitherto these effects have been attributed to the increase in acidity only, and not to the aluminium.

For a number of years the Rhode Island Agricultural Station has attempted to ascertain why different varieties of plants vary so remarkably in their response to liming. For example, under the same conditions, liming may double or triple the yield of barley and have no effect whatever on rye. Nevertheless, the authors found that the addition of acid to ordinary nutrient solutions had as depressing an effect on rye as on barley seedlings. This shows that the toxicity of so-called acid soils is not due to the acid alone, as, if it were so, the effects on the two seedlings would be similar.

The aqueous extract of an acid soil, like the soil itself, affected the two kinds of seedlings very differently, thus showing it to contain a substance which was not present in the ordinary nutrient solution. Sterilisation, dialysis, partial distillation, etc., indicated that this substance was crystalloid. By evaporating the extract, igniting and dissolving the residue in acid, a culture medium was obtained which was much more toxic to barley than to rye. Besides the ordinary nutrients the residue was found to contain silicon, aluminium and chromium. Aluminium being present in large quantities a study was made of the effects of this element by itself, or in combination with silicon, chromium, and other substances. The results led the authors to doubt the hypothesis that acidity is the only, or the main, factor influencing the growth of plants in acid soils.

When an amount of aluminium sulphate equivalent to that found in the soil extract was added to the culture medium, the barley seedlings suffered much more than the rye, but when the same amount of sulphuric acid without aluminium was added the rye suffered as much as the barley. The hydrolysis of the aluminium sulphate gave a hydrogen-ion concentration equal to  $\frac{1}{4}$  only of that obtained with the equivalent amount of free acid. The aluminium sulphate must thus have been the principal cause of the depression in the growth of the barley, and have had a much smaller effect on rye. In other words, the nutrient solution containing the aluminium had the same effect as the aqueous extract of an acid soil.

If aluminium is an important factor in the injurious effects of acid soils, any treatment which renders it less active will prove beneficial. A moist acid soil, upon which most plants died, was thoroughly mixed with the extraordinary amount of 28 tons per acre of acid phosphate, and after two weeks lettuce was planted. This crop could not exist in the untreated soil supplied only with nutrients, but in the soil treated with acid phosphate it gave a maximum crop, exceeding even that obtained when lime was used instead of phosphate.

It was shown that, for a considerable time, the large amount of acid phosphate greatly increased the acidity, yet a crop which usually responds well to liming made its maximum growth on a very acid soil without the addition of lime. The solubility of the aluminium in dilute acetic and carbonic acids had been markedly reduced by the phosphate, as it undoubtedly would have been by lime or lime and phosphate.

The determination of the "active" aluminium may, therefore, prove as useful as the determination of the acidity, and the lime requirements of a soil may be due to the need of lime to precipitate the toxic aluminium just as much as to the need of lime to neutralise its acidity. Indeed, it was found that after sufficient hydrated lime had been added to produce a maximum crop of lettuce, the soil still had, at the end of the vegetation experiment, a lime requirement equivalent to 4 000 to 5 000 lbs. of calcium oxide per acre, in spite of the fact that nearly all the lime had reacted with the soil.

391 — **Nitrates and Nitrification in Relation to Cultural Practices and Plant Growth.**

— NOYES, H. A. (Scientific Proceedings of the Society of American Bacteriologists), in *Abstracts of Bacteriology*, Vol. 1, No. 1, pp. 38-39. Baltimore-London, February, 1917.

Soil bacteriological studies were carried out in an experimental orchard cultivated in different ways — clean culture with cover crop; unploughed, with grass cut and heaped round the trees; unploughed with grass cut and left where it falls. The aims of the experiments were:—*a*) to determine if the behaviour of the trees can be correlated with the activities of the bacteria in the soil; *b*) to determine the effect of this activity on the soil itself.

The results are summarised in the appended table; one season was dry, the other wet.

*Yearly nitrates, nitrification and tree growth (averages of 2 years).*

Data	Unploughed with straw mulch	Clean culture with cover crop	Unploughed		
			Grass cut and piled		Grass cut and left where it falls
			Hillside	Upland	
Circumference gain of trees (cm) . . . . .	5.67	5.10	4.47	4.34	3.55
Nitrates in field (per million) . . . . .	155	432	54	50	49
Nitrates after 6 weeks' incubation (per million). . . . .	1624	1443	2756	1484	1511
Nitrification (per million) . . . . .	1519	1011	2202	1433	1462
Field nitrification (%), . . . . .	17.5	33.5	9	6.5	8

From the results it is seen that: —

1) The nitrates in the field correlate with tree-growth (circumference gains);

2) A lower field nitrate content does not imply lower nitrate content after incubation;

3) The field nitrates, when compared with the nitrates after incubation, give the nitrifying efficiency of the organism under field conditions.

Knowledge of the nitrate content of field soil may throw more light on the activities of nitrifying bacteria than the nitrification test itself.

MANURES  
AND MANURING

392 — **Nitrification as a Measure of the Availability of Different Forms of Calcium Carbonate when Employed as Correctors of Soil Acidity.** — BURGESS, P. S. (Hawaiian Sugar Planter's Experiment Station, Honolulu, T. H.), in *Soil Science*, Vol. IV, No. 4, pp. 327-336, bibliography of 3 publications. Baltimore, October, 1917

Finely ground coral limestone and coral sand were examined for their use as fertilisers; both are identical chemically and only differ in their physical characters. They were applied to acid Hawaiian soils in quantities sufficient to neutralise the acidity. The mixtures were incubated for 20 weeks, and the nitric nitrogen content determined every two weeks. For purposes of comparison similar quantities of the mixture were incubated with the addition of dried blood or ammonium sulphate.

Similar results were obtained with the two lime fertilisers only when no other addition of nitrogen to the soil was made. When another fertiliser

was added, the finely ground coral limestone was  $1\frac{1}{2}$  times as efficacious as the best coral sand. Where no lime is added to the soil, nitrification is more abundant in the presence of dried blood than ammonium sulphate; but where lime of any description is added the reverse is true.

393 - **Changes Occurring During the Storage of Manure.** — RUSSELL, F. J. and RICHARDS, E. H. (Rothamsted Experimental Station), in *The Journal of Agricultural Science*, Vol. VIII, Pt. 4, pp. 494-503, 10 Figs. London, December, 1917.

After having discussed the previous work on the subject, the authors describe a series of investigations, carried out in the laboratory and on farms, which aimed at determining the changes produced in the manure heap, independently of the behaviour of the manure in the soil. To this end a study was made of the variations in the content in dry matter and combined nitrogen which occur during the storage of manure under varying conditions.

There is a great loss of free nitrogen, caused by the continual change from aerobic to anaerobic conditions in the heap and vice versa. The authors suggest that this loss is due to the fact that under anaerobic conditions there is a tendency towards the formation of molecular groups; these groups become unstable as soon as aerobic conditions are produced, or the converse occurs. It is known that, in contact with air, certain carbon compounds formed under anaerobic conditions may change into less complex compounds with elimination of the bivalent methyl groups ( $-\text{CH}_2-$ ). By analogy, therefore, certain complex nitrogen compounds may possibly change into more simple compounds, with liberation of nitrogen. The alternating nitrification and denitrification in the manure heap only represents a special case of this general phenomenon.

For this reason stored manure should be kept under as complete anaerobic conditions as possible, preferably at a temperature of  $26^{\circ}\text{C}$ . Experiments are being made to apply these conditions practically. However this may be, it appears certain that the custom of leaving the manure under the cattle in the stables or under open sheds, until required for use, is the best, wherever possible. No manure heap, however compact and well covered it may be, can fulfill the above conditions; perhaps they might be obtained by keeping the manure in water-tight and perfectly closed tanks at the given temperature. It seems improbable that ordinary manure heaps can be further improved.

394 - **The Problem of Potassium Salts in Italy.** — I. LEVI, M. G. Per l'industria dei sali potassici e del bromo. *Ministero per l'Industria, il Commercio e il Lavoro. Atti del Comitato per le Industrie Chimiche*, pp. 51-60. Rome, 1917. — II. MANZELLA, E. Le acque madri delle saline marittime e il problema dei sali potassici in Italia, *Annali di Chimica applicata*, Vol. VII, Nos. 1-2, 3-4, 5-6, and 7-8; pp. 1-27, 123-144. Rome, 1917. — III. LEVI, M. G. Per l'industria dei sali potassici e del bromo. *Relazione suppletiva. Ministero per l'Industria, il Commercio e il Lavoro, Atti del Comitato per le Industrie Chimiche*, pp. 61-63. Rome, 1917.

I. — The problem of potassium salts in Italy is above all an agricultural one, though many special chemical industries are also interested in it. Besides the German sources, there are others which in the future, may be-

come important, those of Kalucz in Galicia, Catalonia, Ethiopia, and doubtless others, but, as far as possible, the Italian agricultural problem should be solved independently of foreign mineral resources.

Good progress has already been made in Italy in the use of the carbon residue of sugar molasses, which, treated in large quantities, would without doubt yield an appreciable amount of salts. It has been proposed to use similar residues obtained by the evaporation and ignition of the lees of olive oil, but there appears to be some difficulty in the collection and transport of these products, of which there is a considerable quantity, spread over many different and large districts. The ash of plants is well used already, especially in soap factories. The investigations and experiments on the extraction of potassium salts from rock have not yet given quite satisfactory results (1). The sea may yet be used as a source not only of potassium salts, but also of bromine, sodium sulphate and magnesium salts, and in Italy, as for some time past in France, it has been considered as a source of potassium salts. This method would solve two problems at one time — the supply of agricultural potash and industrial bromine.

Italy is eminently a country of salt production. The amount of marine salt obtained annually exceeds 500 000 metric tons, and to this must be added rock salt and that obtained from salt springs. For many years the problem of the extraction of potassium salt from mother-lye of salt springs has been studied. Moreover, according to the communications of the General Office of State Monopolies of the Ministry of Industry, the investigations and experiments carried out since 1915 on the extraction of potassium salts for agricultural purposes from the mother-lye of salt springs has given fairly satisfactory results, and the Italian Office of Finance proposed to start the industrial production of these salts on a large scale from 1916. Work to this purpose is now being carried out at the salt springs of Sardinia from which a large quantity of suitable lye may be obtained.

II. — With regard to Sicily, information is given on the salt springs of Trapani, together with remarks on this product and the more rational use of the mother-lye, the greater part of which is re-circulated to improve the salt deposit of the concentrated "first waters". The volume of mother-lye available at 32.4° Beaumé per metric ton of salt would be 307.258 cubic feet in Sicilian salt springs. Applying this yield to the average salt production of the whole of Sicily a total of 3 789 130 cubic feet is obtained.

Taking this yield as a basis, it may be estimated that, in the other Italian salt springs, the volume of mother-lye available per ton of salt produced would be about 42.38 cubic feet corresponding to a total of 11 978 690 cubic feet.

Analyses of the mother-lyes of salt springs are given, and, after quoting the results obtained by BAIARD, USIGLIO, POHL, MERLE, CRUTI, ASQUINI and LACROIX, who, in water at 30° Beaumé per litre, found a potassium

(1) Though the possibility of leucite production in Italy is unlimited, the present yield is about 1 000 metric tons per annum. (Ed.)

content of 9.06, 18.73, 19.06, 7.69, 23.07, 22.51, 31.28 grams respectively, the author gives the results of an analysis he made of a sample of mother-lye at 31.4° Beaumé, taken from the salt springs of Ronciglio at Trapani. The results are as follows : —

Cations		gm. per litre
—		—
Sodium . . . . .		44.714
Potassium . . . . .		15 585
Calcium : small quantity not estimated . . . . .		—
Magnesium . . . . .		57 978
		118 277
Anions		
—		
Chlorine . . . . .		190 858
Bromine . . . . .		2 382
Sulphuric . . . . .		82.480
		275.729
Total · grams per litre . . . . .		394.006

If the various components were brought to their probable salt combinations the composition of the residue would be :

Sodium bromide . . . . .	gm.	3.067 per litre
Sodium chloride . . . . .	»	111.910 » »
Potassium chloride . . . . .	»	29.719 » »
Magnesium chloride . . . . .	»	146.168 » »
Excess of SO <sub>4</sub> considered to be combined with the calcium . . . . .	»	1.282 » »
Total . . . . .	gm.	394.383 per litre

Calculating the mother-lye at 30° Beaumé, the potassium chloride content would be 25.55 gm. per litre, and from the available mother-lyes of the Italian salt springs it would be possible to extract annually 258 398 cwt. of KCl and 21 205 cwt. of bromine. The 32 salt springs of Trapani which, for various reasons, are best suited for such extraction, would yield 48 427 cwt. of potassium chloride and 3 881 cwt. of bromine.

III. — The potassium deposit of Ethiopia is at Dancalia, nearly 10 miles from the frontier of Italian Eritrea. A little over a year ago a society with a capital of 2 million lire (about £ 80 000) was formed to work this deposit. The salt plain in which the deposit lies, is for the most part, a depression below sea level, and is the bed of an old sea, separated from the Red Sea by volcanic eruptions. The deposit has an area of about 482 square miles. At the surface is found very pure, 90-95 % potassium chloride. The lower layers are composed of 40 to 80 % chloride. Investigations and calculations show this deposit to have a capacity of about 2 million metric tons of 95 % potassium chloride, 140 000 tons of which are on the surface.

Near by there are also deposits of magnesium chloride, and sulphur including about 282 536 to 353 170 cubic feet of the latter. From February to November 1916 this society imported into Italy 2 500 metric tons of 95 % potassium chloride, and, from December, expected to import 1 000 tons monthly. It was certain of being able to supply Italian Agriculture with all the potassium salts required for 1917, and of being able to hold its own against all competition after the war. If this industry really develops as is expected it may cause a great change in the problem of potassium salts for Italy.

In view of a greater development of agriculture in Italy, of the need for bromine which will be felt in the new industries, of the possibility that the Ethiopian potassium chloride deposits will be unable to satisfy the need for potassium salts in Italy, and in view of the fact that changed conditions after the war will allow export trade in these products, the author considers that the extraction of potassium salts and bromine from the mother-lye of Italian salt springs should not be neglected. A careful and detailed financial, technical scheme for the formation in Sicily of works capable of dealing with 3 531 700 cubic feet of mother-lye per annum showed the estimated balance to be :

<i>Cost of Installation . . . . .</i>	<i>4 000 000 lire</i>
<i>Products obtained annually, not including mixed salts</i>	
and a possible production of sodium sulphate :	
39 368 cwt. of magnesium sulphate at 5 lire . .	100 000 »
67 894 cwt. of 80 % potassium chloride at 20 lire	700 000 »
3 937 cwt. of bromine at 400 lire . . . . .	800 000 »
<i>Total . . .</i>	<i>1 600 000 lire</i>
<i>Annual outlay (estimating the mother-lye at 1 lira per</i>	
<i>35.31 cubic feet) . . . . .</i>	<i>900 000 »</i>
<i>Net profit . . .</i>	<i>700 000 lire</i>

Admitting that these figures are estimated with excessive prudence, it is seen that the problem of the method to be adopted for treating the mother-lyes of Italian salt springs is worthy of most serious consideration by the government and manufacturers.

**395 - The Influence of Sodium Nitrate upon Nitrate Transformations in Soils with Special Reference to its Availability and that of other Nitrogenous Manures. —** COLEMAN, DAVID, A., in *Soil Science*, Vol. IV, No. 5, pp. 345-432 + 1 fig., bibliography of 226 publications. Baltimore, November, 1917.

After a full historical and critical review of the question, the author describes his own experiments on the influence of sodium nitrate on the transformations of nitrogen in the soil, by determining its effects upon the ammonification, nitrification, and nitrogen fixation capacity of seven different types of soil (1 very fine sand, 1 loam, 2 sandy loams, 1 clay loam, 1 muck loam, 1 silt loam). The hygroscopic moisture, apparent specific gravity, water-holding capacity, lime requirement, nitrate content and ammonia content of the soils were determined.

It seems certain that the addition of sodium nitrate increases markedly the simplification by hydrolysis of the protein molecules of the soil, for example, cottonseed meal is ammonified to a much greater extent than dried blood. On the other hand, acid phosphate increases the ammonification of dried blood, but potash, in the form of chloride, has little effect.

In alkaline soils sodium nitrate loses its stimulating action to a large extent as regards ammonification; this is due to the increased number of bacteria which assimilate the products of scission by hydrolysis, and to a rearrangement of the soil flora. It is the fungi of the soil which respond the most to applications of sodium nitrate, then the bacteria, the stimulating action of the nitrate being due to an anion.

As regards nitrification, the influence of sodium nitrate is greatest on dried blood, then on cottonseed meal, and, to a lesser degree, an ammonium sulphate, but when present in large quantities it decreases nitrification, and has a similar effect on the nitrogen fixation by *Azotobacter*. In amounts up to 5 000 lbs. per acre, sodium nitrate affects the activity of azotobacteria and azotococci in a similar manner, but in larger quantities it inhibits the activity of azotobacteria. The action of sodium nitrate is most detrimental to nitrogen-fixing bacteria, less so to nitrifying bacteria, and still less so to the ammonifying group.

In short, from the point of view of practical agriculture, sodium nitrate usually has a stimulating action on the activity of ammonifying and nitrifying microorganisms, but inhibits that of the nitrogen-fixing group. Nevertheless, if sodium nitrate is applied rationally there will be no danger of a toxic action, and there is reason to believe that the assimilation of soluble mineral fertilisers contributes to the recovery of the nitrogen supplied to the soil.

396 - **Experiments on the Bacterisation of Peat for Soil Fertilising Purposes.** — JONES, D. H. (Scientific Proceedings of the Society of American Bacteriologists), in *Abstracts of Bacteriology*, Vol. 1, No. 1, pp. 43-44. Baltimore-London, February, 1917.

Peat bacterisation experiments were carried out with the object of verifying the claims made by Prof. BOTTOMLEY for "humogen" (1). Five 1 bushel lots of peat were taken; to three was added lime in varying quantities and they were then inoculated with rich broth cultures of soil bacteria; the 4th. lot was inoculated only with the same culture, and the 5th. kept as control. All were incubated at 25° C. for one month, moistened and aerated occasionally. They were then autoclaved for 1 hour, after which rich cultures of *Azotobacter*, *Pseudomonas radiculicola* and cellulose fermenting bacteria were added to all except the control, and the lots incubated at 25° C. for two months. Chemical tests and bacterial counts were made from time to time.

The different lots of peat thus obtained were mixed in 0.5, 2 and 10 percentages with a poor soil, the mixture placed in pots and radishes sown.

(1) See R. 1917, No. 714. (Ed.)

After 1 month the growth and greenness of the foliage was markedly in favour of the 10 % bacterised peat. After 3 months the results were, as a rule confirmed, both as regards growth of roots and of leaves, in favour of heavy applications of bacterised peat, up to an increase of more than 100 % in plant growth. The following results were obtained : —

Soil containing	Weight of roots	
	Bacterised peat	Unbacterised peat (control)
	gm.	gm.
0.5 % of peat . . . . .	39.33	35.5
2 % „ „ . . . . .	57.75	41.75
10 % „ „ . . . . .	135.25	63.25

The addition of lime had little, if any, effect.

To sum up, the bacterial treatment of peat seems to make the peat useful as a fertilizer, but the large quantities necessary to produce appreciable results excludes its general use as a fertiliser on account of the expense entailed.

399 — Studies on Inulin in Plants : I. Its Formation ; II. The Changes it Undergoes in the Resting Tuber of the Jerusalem Artichoke. — COLIN, H., in the *Comptes rendus des Séances de l'Académie des Sciences*, Year CLXVI, I. No. 5, pp. 224-227. February 4, 1918 and II. No. 7, pp. 305-307. February 18, 1918, Paris.

I. — The formation of inulin in plants is not yet well understood ; according to some authors, inulin is formed in the leaves, and then migrates unchanged into the roots or tubers ; others think that the inulin-storage organs only receive sugar from the leaves, the sugars afterwards condensing to form inulin.

Chemical examination of several inulin-containing plants, particularly the Jerusalem artichoke, has lead the author to believe that there is no question of the immediate elaboration of inulin by the leaves and its migration unchanged to the underground organs. It is osmotic pressure (MAQUENNE'S law) that controls the storage of inulin as it does the storage of saccharose ; the leaves only form sugars which are condensed either during their passage down the stem or only in the roots or tubers.

II. — Since 1867, DUBRUNFAUT (1) has recorded that Jerusalem artichoke tubers gathered in March give juice with a positive rotation, while those gathered in October give a decidedly laevorotary juice ; he attri-

(1) DUBRUNFAUT, *Comptes rendus*, Vol. LXXIV, 1867, p. 764. (*Author*)

butes that difference to the transformation of the inulin into crystallisable sugar during the rest period.

In reality, saccharose is always present in tubers undergoing formation, while the proportion is only augmented during the winter months.

DUBRUNFAUT thought that "inulin changed into two isomers, crystallisable cane sugar and an uncrystallisable sugar, optically inactive, and similar to that found in the fermentation of inverted sugar". This conclusion is not entirely justified; in fact, the direct rotation of the juice obtained in February to March is not more than  $+10$ ; correlatively, after inversion the rotation reaches  $-55$  at  $15^{\circ}\text{C}$ ; thus there exist at that period in the tubers, laevorotary principles, giving laevulose on hydrolysis, and which almost completely neutralise the positive rotation of the saccharose. These levulosanes differ greatly from the primitive inulin; their total rotatory power, ranging from  $-25$  and  $-30$ , is less than that of inulin ( $-40$  according to TAURET); but they can be hydrolysed by invertine and ferment, in consequence, in the presence of yeast. If sucrase is added to the juice of the Jerusalem artichoke, the reducers increase progressively while, at the same time, the power of rotation decreases; the saccharose is hydrolysed more rapidly than the levulosanes. All the carbohydrates are hydrolysed. When the juice is left standing in presence of an antiseptic, they transform spontaneously, but much more slowly.

These facts show why, in the distilling industry, Jerusalem artichoke tubers treated in October require a previous hydrolysis by acids, whilst those of tubers collected after winter may be fermented at once.

One part of the inulin changes, therefore, to *saccharose* in the tuber; the other part is degraded progressively to form levulosanes with an optical rotation lower, in absolute value, to that of inulin.

These phenomena are not limited to the Jerusalem artichoke; they also occur in chicory, in which they were observed by MM. WOLFF and GESLIN (1).

400 - Studies on the Cyanogenetic Compounds of Sorghum. — WILLAMAN J. J.: I. The Estimation of Hydrocyanic Acid and the Probable Form in which it Occurs in *Sorghum vulgare*; II. The Effect of Anaesthetics and of Frosting on the Cyanogenetic Compounds of *Sorghum vulgare*. *The Journal of Biological Chemistry*, Vol. XXIX, No. 1, pp 25-36, pp. 37-45. Baltimore, February, 1917.

I. — The methods generally in use for the estimation of cyanogenetic compounds in vegetable tissues (based on the hydrolysis of the cyanogenetic glucoside and the amount of hydrocyanic acid thus formed) are of doubtful accuracy, partly on account of the difficulty of obtaining complete hydrolysis with acids, partly on account of the partial retention by the tissues of the hydrocyanic acid during distillation, which is neither prevented by the addition of tartaric acid, nor diminished by distillation under reduced pressure.

*Sorghum vulgare* contains hydrocyanic acid in two forms: — a glucoside (dhuririn) and a non-glucosidic cyanide compound, the nature of which is

(1) See R., Dec. 1917, No. 1137 (Ed.).

as yet unknown. It is probably the latter which causes poisoning of live-stock. The best method of obtaining hydrolysis of the dhuririn is by autolysis, which occurs very rapidly at 45° C. The non-glucosidic cyanide may be separated from the glucoside by grinding the leaves in the presence of 5 % tartaric acid to prevent enzyme action and then distilling. By these means only the hydrocyanic acid from the non-glucoside substances is obtained; the latter are more unstable and decompose when boiled with a 5 % tartaric acid solution.

II. — Sorghum leaves exposed to the action of chloroform, ether, and alcohol, yield more hydrocyanic acid, both glucosidic and non-glucosidic, than normal leaves. The anaesthetics thus stimulate the hydrolytic as well as the synthetic action of the glucoside enzymes (this is a case of synthesis caused by enzymes *in vitro*). Enzyme powder prepared from chloroformed leaves was about 25 times as active towards amygdalin as the powder from untreated leaves. An examination of leaves which had been exposed to frost in the field and of leaves which had been subjected to a temperature of 7°C. showed that frost causes an increased yield of both glucosidic and non-glucosidic hydrocyanic acid. This is due partly to rupturing of the cells, and partly to disturbed enzyme equilibrium.

401 — **Analysis of Zamia Palm Nuts and Leaves.** — *The Agricultural Gazette of New South Wales*, Vol. XXVIII, Pt. 12, p. 865. Sydney, December, 1917.

An analysis made at the Chemist's Branch of the Department of Agriculture of New South Wales gave the following results :

	Kernel	Leaves
Moisture . . . . .	81.79 %	76.67 %
Ash . . . . .	1.07	0.99
Ether extract . . . . .	0.18	0.21
Fibre . . . . .	4.74	6.18
Albuminoids . . . . .	0.03	2.64
Carbohydrates . . . . .	12.19	13.31

402 — **The Chemical Composition of the Potato Plant at Various Stages of Growth.** — See No. 415 of this Review.

403 — **The Growth of Isolated Plant Embryos.** — BUCKNER, G. DAVIS and KASTLE, JOSEPH, H. (Laboratory of Chemical Research, Kentucky Agricultural Experiment Station, Lexington), in *The Journal of Biological Chemistry*, Vol. XXIX, No. 2, pp. 209-213. Baltimore, Md., March, 1917.

In their experiments the authors attempted to nourish embryos of Lima beans (*Phaseolus lunatus*), deprived of the cotyledons, with different compounds. Sugars (2 % solutions of glucose, saccharose, lactose, raffinose, mannite and maltose) caused growth, but starch or Hopkins' plant food had no influence. It has been shown that cotyledons which give no characteristic reaction for reducing sugars cause no growth, whereas the same cotyledons, when supplied with sugar, give a good growth. It was further

shown that the cotyledons of lima beans that have germinated and contain reducing sugars may also support the growth of an isolated embryo.

The results seem to show that growth of the embryo occurs wherever glucose or a carbohydrate giving a hexose on hydrolysis is present. When these substances are absent no growth results. It was further shown that the dry Lima bean does not contain the plant food necessary for the growth of its own embryo, but that the green cotyledons of a germinated bean do contain the food necessary for the normal growth of the plant.

404 - Variations in the Development of Secondary Rootlets in Cereals. — WALWORTH<sup>1</sup> E. H. and SMITH, I. H., in the *Journal of the American Society of Agronomy*, Vol. X, No. 1<sup>2</sup> pp. 32-35, Lancaster, Pa., January 20, 1918.

The method adopted was to sow 100 or more grains from each variety studied in pots containing pure quartz sand, which were kept in a greenhouse. The secondary rootlets were counted when the plumule was from 1 to 2 inches high. The results, which confirmed those of Mr. R. G. WIGGANS (*Journal of the American Society of Agronomy*, Vol. 8, No. 1, pp. 31-37; 1916), showed that the number of secondary rootlets is by no means constant for a given variety, but varies with the individual, so that counts made from samples chosen at random usually give a frequency distribution represented by a fairly normal curve.

In *oats* the number of secondary rootlets varies from 0 to 5; each variety has a tendency to a high or low number of secondary rootlets, the number of frequency being 2 for some and 3 for others.

Of 11 varieties of *wheat* examined, 9 had a number of frequency equal to 2; in the two others it was equal to 4.

In *barley* the maximum number is 7, the number of frequency being 3 in some varieties and 4 in others.

The number of secondary rootlets is also variable in *maize*.

The range of variability is less in pure-line selections of oats than in the ordinary varieties. This is also true for wheat, with the exception of Turkey hybrid No. 509, which was more variable than the other selected varieties, perhaps because of its hybrid origin.

405 - The Selection and Hybridisation of Cereals in Alaska, U. S. A. — GEORGESON C. C. *Annual Report of the Alaska Agricultural Experiment Stations 1904-1915*. Washington, 1905-1916.

PLANT  
BREEDING

The introduction of the cultivation of cereals in the districts bordering on the arctic polar circle is of both practical and scientific importance.

In Alaska there is a great difference between the climate of the coast and that of the interior of the country. Along the Pacific, to the south of the high chains of the Alaska Range and of the St. Elias and Coast Ranges, the summer is cool, but the winter mild, so that at Sitka, for example, the average annual temperature is almost the same as that of Washington, D. C. In this district, the cool summers, abundant rainfall, and frequent clouds, are favourable to the growth of vegetables and grasses but unfavourable to that of ordinary crops, especially cereals, which do not ripen. In the interior, however, along the Yukon valley, between the coast Sierra

and the mountain groups of the southern sector (Endicott Range), the climate is decidedly continental, with dry, very cold winters and short summers, but nevertheless capable of causing rapid plant growth owing to the large number of hours of sun daily (18 to 20).

AGRICULTURAL STATIONS. — Alaska possesses 6 : —

1) *Sitka*, on the western coast of Baranof Island, a little above the 57th. parallel ; fruit trees and bushes are studied there.

2) *Kodiak*, on the eastern coast of Kodiak Island, near the 58th. parallel, concerned with animal husbandry.

3) *Kenai*, on Cook Inlet, near the 61st. parallel ; marsh plants, fodder plants and animal husbandry.

4) *Copper Center*, in the valley of the Copper River, about 100 miles from the coast. This Station, which dealt with cereals and marsh plants, was closed in 1909, and all the material received was transferred to *Fairbanks* and *Sitka*.

These four districts have a coastal climate, with mild winter but cool, rainy summers.

5) *Fairbanks*, in the Tanana Valley, a tributary of the right bank of the Yukon, near the 65th. parallel ; it deals with cereals, fodder plants, hoed crops, the breeding of resistant livestock for the interior.

6) *Rampart*, on the Yukon River, near the 66th. parallel ; it is the most northern station and is concerned with cereals and forage Leguminosae.

The two localities are in the district having a continental climate.

INTRODUCTION, ACCLIMATISATION AND IMPROVEMENT OF CEREALS IN ALASKA. — The work is organised as follows : —

1) *Acclimatisation experiments* of the greatest possible number of varieties from districts differing greatly from each other, situated especially in northern countries where the conditions for cereal growing are similar to those found in Alaska.

2) *Selection* : after the varieties capable of developing normally in the country have been determined, each is selected individually with a view to isolating lines having the most desirable characters, chief of which is earliness.

3) *Hybridisation* : in the successive individual selection, earliness is often accompanied by low yield, weak culms, etc. Attempts are made to obviate these faults by crossing early types with those which yield well and have strong straw, etc., so as to unite in one type the positive characters and eliminate the negative ones.

The work on cereals was first started at Kenai, Sitka, Copper Center, Fairbanks and Rampart, and then limited to the two last because at Sitka and Kenai, the wetness and low temperatures of summer prolong the period of growth to such an extent that the crops are exposed to the first, destructive, autumn frosts when, even under the most favourable circumstances, they have barely reached the milk-ripe stage. As has already been said, the Copper Center Station was closed in 1909. Varieties of barley and

oats have been tested at Sitka, rye and winter wheat at Kenai. The varieties tested were: —

- 1) *Barley*: — Erhard Fredenksen; Naked Barley S. P. I. 17 e. Section Plants Imported, U. S. Dept of Agric.) No. 20 909; Donnes Barley S. P. I. No. 20 608; G. I. 592 (from Norway).
- 3) *Oats*. — Erhard Frederiksen.
- 3) *Rye*: — Excelsior; Schlansted Techit'n.
- 4) *Winter wheat*: — Winter wheat; Yaroslaf

At the Copper Center Station, a little more inland, more satisfactory results were obtained than at Sitka and Kenai, and perhaps some varieties, especially of barley, could be grown successfully in the more sheltered parts of the Copper Valley. In any case precautions must be taken against summer frosts, which may destroy the crops completely, as occurred in 1908.

In the Yukon Valley the conditions peculiar to the northern climate oblige the selector to subordinate yield to earliness, so as to allow the varieties selected to complete their growth (from sowing to the ripening of the seeds) in the short interval of 70 to 90 days between the last spring frost and the first, destructive autumn frost. The results obtained for the different varieties of cereals were: —

1) *Winter wheat*, — Numerous varieties were introduced from the extreme northern countries — North Russia and Siberia, as well as the highest plains of the Himalayas. Mention may be made of the varieties Landomirka, Beloglina, Klondike (Canada), Pullman Hybrid No. 28, Wisconsin Pedigree No. 22, Bluestem, Pullman Hybrid No. 143, Pullman Winter Fife, Pullman Fortyfold. In the Upper Yukon Valley three climatic factors are very injurious to winter wheat: —

- a) the winter cold which kills the young plants;
- b) the alternate freezing and thawing in spring which heaves the plants;
- c) the early autumn colds which prevent ripening; the first destructive frost usually occurs towards the end of August.

Kharkov gave the best results of all the varieties tested. It is a slightly bearded wheat and a native of Russia introduced by the Federal Department of Agriculture. It ears in July and at least a part of the harvest always ripens completely by the beginning of September. In spite of its resistance to cold a large percentage of the young plants always die during the winter; for example, in 1913-1914, only 5 % of the young plants survived the winter. Winter cereals should be sown where the snow is thickest and lasts longest, so that it may protect the young plants, first against low temperatures, then against alternate freezing and thawing. In spite of nine years' selection the resistance to cold of the Kharkov variety has in no way increased, and, if the hybridisation experiments now in progress give equally negative results, winter wheat in Alaska will be superseded by rye, which is much more resistant to cold.

2) *Winter rye*. — Rye gave much better results than wheat. Whereas, in 1913-1914, 95 % of the young plants of Kharkov wheat were killed, the losses in the different varieties of rye varied from 10 to 25 %. The best of the many varieties studied were Excelsior, Amber, Giant

French, Brandon, Monster, No. 281, No. 1134, No. 12890, North Dakota, No. 959, Station No. 195, and Irkoutsk, all fairly equal as regards resistance to cold but differing largely in earliness. In 1914 the dates of ripening were:—

Irkoutsk, Giant French, Amber, No. 959, Monster,		
Station No. 195 . . . . .	August	12
Brandon . . . . .	"	14
No. 1134, No. 12890, No. 281 . . . . .	"	24

As regards *yield*, mention may be made of that given in 1914 at Fairbanks by the variety Winter Rye No. 19556, which, on a  $\frac{1}{8}$  acre plot gave a yield of 1520 lbs. per acre.

In Alaska the vegetative period of rye exceeds 13 months (1); it is sown towards the end of July and harvested at the beginning of September of the following year. It is, therefore, necessary to obtain varieties which ripen earlier so that the grain produced during the year may be used for sowing. The following hybrids are being tested:—Station No. 195  $\times$  North Dakota No. 959; Giant French  $\times$  Amber; North Dakota No. 959  $\times$  Giant French.

3) *Spring wheat*. — On the whole the results obtained with spring wheat are not very satisfactory. As sowing is not possible before May, there remain barely 90 days for ripening before the autumn frosts, so that the indispensable character required is earliness. None of the varieties studied ripen for certain each year, but the best were Chogot and Irkoutsk, the vegetative period of which lasted only 88 days (May 1st to August 27th) in 1914. These two wheats, introduced by the Federal Department of Agriculture, come from the Agricultural Station of Tulun (Government of Irkoutsk, Siberia). The Russian bearded wheat No. 306 is almost as early as these two, and the Russian wheat H. G., of vigorous growth, ripens four days later. Then come Ulka, Velvet Chaff, Ladoga, Red Fife, Romanov, Marquis, Early Java, which usually only ripen once in five years, as was the case in 1912 at Rampart, where the varieties Red Fife, Romanov and Wild Goose gave from 55 to 60 bushels of grain per acre.

The following crossings were made:—

a) Red Fife  $\times$  Saskatchewan; b) Chogot  $\times$  Saskatchewan; c) Chogot  $\times$  Velvet Chaff; d) Chogot  $\times$  Irkoutsk; the 1914 hybrids were no earlier than the parent plants, but the ears were larger and more compact, each spikelet containing 5 or 6 grains; e) Red Fife  $\times$  Ladoga; two yet unstable hybrids were obtained which still continue to split up into bearded and unbearded individuals, but they are earlier than the parent plants, thus fulfilling the aim in view.

4) *Spring rye*. — At Rampart, on May 1, 1915, were sown the three varieties Irkoutsk (from Tulun, Siberia), Gesselberg (from Tulun), and Mammoth. The first ripened on August 19. Gesselberg almost immediately after, and Mammoth ten days later. All the spring ryes were inferior to

(i) The abstract No. 635 of R. 1916 describes a variety of rye of the Upper Valley of the Dora Riparia (Italy) which remains in the ground for a period which may exceed 13 months. (Ed.)

the winter ryes in both earliness and yield. Attempts were made to improve them by selection and hybridisation. The cross Irkoutsk  $\times$  Mammoth gave, in the  $F_1$ , hybrids with well-filled heads and the earliness of Irkoutsk.

5) *Oats*. — Experiments have been made with many varieties of oats from northern districts, especially from Scandinavia, Finland, Russia and Siberia. The varieties which appeared most suitable were subjected to continuous individual selection with the purpose of developing the character "earliness". The best results were obtained with the varieties Finnish Black, Norwegian, South Dakota No. 637, Canadian 444 (from California), and Sixty Day, which ripen, on an average in 90 to 92 days, in time to avoid the first destructive frosts. Good results were also obtained with Copperfield, New Swedish, Hansen, Black Tartarian, and Banner, although they are a little late. The varieties Minnesota No. 261, Orlov, Ontario, Ruakura, Russian No. 409, and Beliak (from Yakoutsk, Siberia), have little chance of succeeding in Alaska.

Very little data on *yield in grain* is available. At Fairbanks in 1912, the varieties Sixty Day, Finnish Black, and Banner yielded 85, 90 and 100 bushels per acre respectively, whereas at Rampart, the yields were not quite half these amounts. It should be noted that all these figures refer to small, chosen plots, with the most favourable exposure possible.

Although the results obtained by individual selection and acclimatization with the varieties Finnish Black, Copperfield and South Dakota, leave very little margin for subsequent improvement, hybridisation experiments were carried out some of which gave absolutely positive results. Thus, for example, the hybrids 25 A-1 and 25 A-3, which ripen one day earlier than Finnish Black oats, give as many as 120 grains per head, and, in three years only, are sufficiently stable. Both are derived from the cross Copperfield  $\times$  Toholampi. Copperfield is a grey mutation from the Finnish Black variety, from which Toholampi is also derived by selection in pure lines.

6) *Barley*. — Owing to the relative shortness of its period of growth, barley is undoubtedly the cereal most suited to Alaska. Its yields in grain and straw are fairly high, and the nourishing grain, besides being an excellent food for cattle may also be used for making bread. The acclimatization experiments have given a large percentage of varieties capable of ripening completely. The best results were obtained with: —

*Pamir* S. P. I. No. 18922, a bearded barley, native of Central Asia, where it does well at altitudes of from 900 to 1300 feet, is one of the earliest varieties of barley of the world; at Rampart it ripens, on an average, 76 days after being sown, but yields little.

*Champion*, a beardless barley of very vigorous growth.

*Manshury*, also excellent, early productive, with strong straw, but long, stiff, sharp awns.

*Chittyna*, a beardless barley, productive and with strong straw, but too late; it was isolated in 1906 at Coldfoot, Alaska.

More or less satisfactory results were obtained with:

*Beardless* No. 19852; *Hull-less* No. 19851; *Uvjala* and *Finland* (both natives of Dickkursby, Finland); *Swedish* No. 19557; *Jakoutsk* G. I. 498 (native of Siberia); a Russian variety, S. P. I. No. 2786, which, together with a few others, resisted the terrible frost of July 21, 1908.

All the barleys studied were from northern countries, with the exception of Barbary G. I. No. 659, a native of North Africa which in 1911, at Rampart, ripened only one week later than the Pamir variety.

The hybridisation of barley, both in its scope and the results obtained, is much more important than that of other cereals. The three characters essential to a thoroughly satisfactory barley in Alaska are: —

- a) *Earliness*, for the usual reasons already mentioned;
- b) *Absence of awns*, as their presence prevents the feeding of barley in the ear to cattle;
- c) *Strong straw*, to resist lodging.

The best of the numerous hybrids obtained are: —

*Hull-less* S. P. I. 12 709  $\times$  *Swedish* S. P. I. 19 557. The second used as male parent, was chosen because of its earliness, but it has awns. *Hull-less* is a good variety in every way, but is late. The hybrids have slightly pointed glumes, and may be said to be beardless. They are nearly as early as Pamir barley (vegetative period = 80 days), and have very resistant straw.

*Chittyn*  $\times$  *Oderbucker*, a cross made in 1909. The descendants were mixed as regards the presence of awns, but in 1914, the percentage of bearded ears had dropped to 10-15%; and it is probable that, if selection is continued, a stable, beardless type will eventually be obtained. This hybrid gave good yields in grain and straw.

Many crosses were also made between the earliest barley, Pamir, and other satisfactory varieties. Four of these hybrids, now stable, ripen very quickly (towards the middle of August), and three are beardless.

CONCLUSIONS. — All winter and spring cereals may be grown in the valley of the Yukon and its tributaries, where the short, but relatively warm and dry summer, allows them to grow and ripen in the three months' interval between the last destructive spring frost and the first autumn one, *i. e.*, between the end of May and the end of August.

The first place is held by barley, some varieties and hybrids of which seem to unite in good proportions the most essential characters strong straw, high yield, and absence of awns (1).

406—The Inheritance of Glume Length in *Triticum polonicum*. A Case of Zygotic Inhibition. — BACKHOUSE, W. O., in the *Journal of Genetics*, Vol. VII, No. 2, pp. 125-133, 5 figs. Cambridge, 1918.

PUBESCENCE. — Polish wheat (*Triticum polonicum*) is characterised by long glumes, which may reach a length of 40 mm.; the average length is 29 mm., as compared with 10 mm. in ordinary wheat. The author (Economic Botanist to the Argentine Government), having noted in 1911,

(1) According to an approximate estimation there are, in Alaska, 30 000 square miles of tillable land. It is not easy to determine how much of this area is suitable to the different cereals nor is it possible to say whether it would be practical to produce cereals in competition with the neighbouring market of the United States. Nevertheless the results of the experiments carried out so far are of great importance for agricultural science and also because some of the selected varieties obtained by hybridisation might be advantageously introduced and acclimatised in the vast lands of Russia, Siberia and Canada. (*Ed.*)

that in a collection of varieties of *T. polonicum* belonging to Mr. PH. DE VIL-MORIN at Verrières (France), there were none with perfectly smooth glumes, and that, the shorter the glume, the more felted did it appear, proposed to study the influence of the length of the glumes on their pubescence. To this end he crossed, in 1912, a variety of *T. polonicum* having an average glume length of 29 mm., and very faintly pubescent, with a variety of *T. durum* called "Kubanka", a smooth variety with an average glume length of 12 mm. The first generation had glumes of intermediate length (18 to 19 mm.), and was much more pubescent than the parent *T. polonicum*.  $F_2$  had plants with fully pubescent ears.

The author divides the hybrids of  $F_2$  into 2 groups as regards length of glume :—

- 1) short glumes (homozygotes), 10 to 14 mm. long;
- 2) long glumes (homozygotes), 22 to 31 mm., and intermediate glumes (heterozygotes), 14 to 22 mm. long.

In  $F_2$  there were 172 long and intermediate plants, and 55 short ones; the theoretical numbers would be 170.25 and 56.75, corresponding to the Mendelian ratio 3 : 1. Of the 55 short-glumed plants, 40 were felted, 15 smooth; the theoretical numbers would be 41.25 and 13.75, according to the Mendelian ratio 3 : 1, showing predominance of the character "pubescence".

Considering the plants with glumes from 14 to 21 mm. long as heterozygotes, only 15 out of 85 could called really felted. The plants with long glumes (22 to 31 mm.) were all smooth, like the parent Kubanka.

Crosses between these plants with long glumes with the parent Kubanka sometimes gave, in  $F_2$ , a mixture of rough and smooth plants showing, in the short-glumed group, the usual ratio of 3 : 1.

These results show that, in *T. polonicum*, long glumes inhibit pubescence, so that they remain smooth in spite of the presence of the factor determining pubescence. To obtain felted glumes, the length must be reduced.

PIGMENTATION. — The same variety of *T. polonicum* (with glumes from 28 to 29 mm. long, whitish, smooth) was crossed with a variety of *T. turgidum*, derived from Rivet wheat, which it resembles (glumes 11 mm. long, black, felted).

The glumes of the  $F_1$  were intermediate in length (14 to 17 mm.), white, or slightly tinged, fairly felted. In the  $F_2$  there were 514 long or intermediate glumed plants, and 178 short-glumed ones; the theoretical numbers would be 519 and 173 in accordance with the Mendelian ratio 3 : 1.

The same phenomenon is observed in the coloration of the glumes as in their pubescence, except that the character "black coloration of glumes" is recessive. In the short-glumed group (8 to 13 mm.) of 178 hybrids, 129 were white or tinged and 49 coloured; the theoretical numbers, corresponding to the Mendelian ratio, would be 133.5 and 44.5. All the long-glumed hybrids were white or tinged.

It may, therefore, be concluded, that the length of the glumes has an inhibitory effect on their pigmentation.

407 - **Oat Selection by Pure Lines at the Agricultural Experiment Station of Highmoor, Maine, U. S. A.**—SURFACE, FRANK M. and ZINN, JACOB, *Thirty-second Annual Report of the Maine Agricultural Experiment Station*, pp. 97-148. Orono, Maine, 1917.

The work described was begun in 1910 at Highmoor Farm, with 146 plants chosen from 18 of the most common commercial varieties, each being used as stock for a pure line.

In 1915, the best material, from which the poorer types had been gradually discarded, was reduced to 12 lines:—

Maine Nos. 355, 281, 351, 230, 307, 286, 357, derived from the Banner variety;

Maine Nos. 340, 337, 336, 346, derived from the Irish Victor variety;

Maine No. 247, derived from the Imported Scotch variety.

As is seen in the appended table, the selection results were distinctly positive, *all* the pure lines being markedly superior to the original varieties Banner, Irish Victor and Imported Scotch.

*Yield in grain of the pure lines compared with the original commercial varieties.

<i>Average</i>		<b>80.8</b>	<i>Average</i>	<b>75.2</b>

As regards the shape of the panicle, the characters of the caryopsis, etc., the pure lines closely resemble the original varieties. The changes in physiological characters which result in higher yield are, therefore, not necessarily associated with morphological characters.

The selected types are not only distinguished by a high yield, but also by the regularity and uniformity with which they ripen, points not always found in commercial varieties, many of which give, at the same time, early plants, over-ripe at the time of harvest, thus losing their grain easily, and

plants which are still green at harvest time, thus reducing the yield, and giving a product of unequal appearance. In all the selected plants the vegetative period (from sowing to harvest) lasts, on the average, 106 days with a minimum of 103 for Maine Nos. 340 and 337, and a maximum of 109 for Maine No. 357.

By its yield, strong straw (almost totally resistant to lodging), and the weight of its grain (1 000 weigh 40.30 gms. as against an average of 37.72 gms. for the 12 lines), Maine No. 340 is the type best adapted to the soil and climatic conditions of Highmoor.

The highest net yield was given by the line Maine No. 355 (86.6 bushels per acre), which is distinguished by its low hull percentage (27.76 %, as compared with 28.45 % for the 12 lines). On the other hand, its grain is light (35.49 gms. per 1 000) and it is somewhat subject to lodging, especially in heavy soils.

The other lines, though excellent and worthy of further trial, are nevertheless inferior to the two above-mentioned types.

The experiments are being continued with the aim of : — 1) isolating further new lines ; 2) improving those already obtained by the removal of undesirable characters ; 3) determining in each case the districts in Maine and other states best suited to each of the types which is being selected and propagated.

408 — **Genetic Study on the Awns of a Variety of Six-Rowed Barley.** — IKENO, SEIITIRO, in *The Botanical Magazine*, Vol. XXXI, No. 370, pp. 263-267. Tokyo, October, 1917.

All the spikelets of the Japanese variety of six-rowed barley (*Hordeum sativum hexastichum*) known as "Kinukawa", have awns, which are longer in the central than the side rows.

To study the inheritance of these awns the author crossed, in both directions, the Kinukawa variety with another variety of six-rowed barley called "Noghenasi", generally beardless, but sometimes having, except on the upper part of the ear, median spikelets with very short awns.

In the  $F_1$  generation the hybrids Kinukawa  $\times$  Noghenasi and Noghenasi  $\times$  Kinukawa both had median awns shorter than those of the parent-plant Kinukawa, whereas the lateral awns, even in the same ear, varied considerably, being : — 1) very short ; 2) entirely absent ; 3) reduced to a slight prolongation of the glume.

In the  $F_2$  there were many forms : — 1) ear completely bearded ; 2) ear semi-bearded (awns on the median rows only) ; 3) lateral awns varying, as in the hybrids of  $F_1$ . Moreover, in each group, the length of the awns varied considerably.

In the  $F_3$  only 4 of the 321 plants of the  $F_2$  gave constantly bearded progeny (like the parent Kinukawa), and only 6 gave progeny constantly beardless (like the parent Noghenasi). The average between 4 and 6 gives the Mendelian ratio 5 : 321, equal to the ratio 1 : 64, observed in cases of tri-hybridism.

The author admits the presence of three factors, or genes, which he calls A, E, and I respectively. Even in the absence of these three factors (*i. e.*, in individuals having the gametic formula *aa ee ii*), two varieties

of very short awns (median and lateral) may develop, but the presence of either **A** or **E** increases the length of the awns, and the simultaneous presence of **A** and **E** gives them the maximum development characteristic of the completely bearded type, Kinukawa, which has the formula **AA EE II**. On the other hand, the inhibitory factor **I** prevents the formation of awns on the lateral rows, while the median rows have long awns, in accordance with the formula **AA EE II**.

In the beardless parent, Noghenasi, (with formula **aa ee II**), the factor **I** suppressed not only the lateral awns, but also, partially or totally, the median awns. By crossing Kinukawa (**AA EE II**) with Noghenasi (**ee aa II**), were obtained in  $F_1$  hybrids with the formula **Aa Ee II**, in which the shorter median awns and the different behaviour of the lateral awns are easily explained by the presence of **A**, **E** and **I** in the heterozygous state.

In the  $F_3$  there are 64 gametic combinations, which may be divided into three groups:—

1) *Completely bearded ears*, in which the factor **I** is entirely absent; they number 16:— 1 plant with the formula **AA EE II** (Kinukawa type); 2 **AA Ee II**; 2 **Aa EE II**; 4 **Aa Ee II**; 1 **AA ee II**; 2 **Aa ee II**; 1 **aa EE II**; 2 **aa Ee II**, 1 **aa ee II**.

2) *Semi-bearded or beardless ears*, in which the factor **I** is homozygous; they number 16: 1 **AA EE II**; 2 **AA Ee II**; 2 **Aa EE II**; 4 **Aa Ee II**; 1 **AA ee II**; 2 **Aa ee II**; 1 **aa EE II**; 2 **aa Ee II**, 1 **aa ee II** (Noghenasi type).

3) *Plants in which I is heterozygous*; they number 32:— 2 **AA EE II**; 4 **AA Ee II**; 4 **Aa EE II**; 8 **Aa Ee II**; 2 **AA ee II**; 4 **Aa ee II**; 2 **aa EE II**; 4 **aa Ee II**; 2 **aa ee II**.

The problem of the distribution of the  $F_2$  plants among these three groups may be solved by an examination of the progeny in  $F_3$ . It is clear that the plants of groups 1 and 2 will produce exclusively bearded and beardless plants respectively, whereas those of group 3, in accordance with the Mendelian laws, will give mixed progeny composed of both entirely bearded and semi-bearded forms. The results of an analysis of  $F_3$  were as follows:—

*Composition of the  $F_1$  generation.*

	Number of plants		Percentages	
	found	calculated	found	calculated
Group I . . . . .	69	80.25	0.9	1
Group II . . . . .	88	80.25	1.1	1
Group III . . . . .	164	160.50	2.0	2
Totals . . . . .	321	321.00	4.0	4

There is, therefore an almost perfect agreement between the figures found and those calculated.

It has already been shown above that of the 16 hybrids of groups 1 and 2 of the  $F_2$ , 4 hybrids of each group (*i. e.*  $\frac{1}{4}$ ) remain constant even in the  $F_3$ ; these are: **AA EE II**, **AA ee II**, **aa EE II**, **aa ee II**, (group 1); **AA EE II**, **AA ee II**, **aa EE II**, **aa ee II** (group 2), whereas, on the contrary, no plant

of group 3 remains constant in the  $F_3$  owing to the presence of the factor I as a heterozygote. Experiments on this subject gave the following results: —

Group I (69 individuals)		Group II (88 individuals)		Group III (164 individuals)	
Number of constant individuals		Number of constant individuals		Number of constant individuals	
found	calculated	found	calculated	found	calculated
21	$17.25 \left( = \frac{69}{4} \right)$	23	$22 \left( = \frac{88}{4} \right)$	0	0

CONCLUSIONS: — 1) Three factors A, E, I, are concerned, of which the first two are found in the bearded parent Kinukawa, and the third in the beardless parent Noghenasi. Even in the absence of these three factors *short* median and lateral awns may be formed, but in the presence of A or E the awns are longer and, in the presence of both at the same time, the awns may be as long as those characteristic of the variety Kinukawa.

2) The factor I is inhibitory; when homozygous it suppresses the lateral awns, but does not entirely prevent the formation of median awns, which are sometimes found even in the beardless Noghenasi plants of the formula aa ee II; when heterozygous, it produces a great variety of lateral awns, sometimes even on the same ear.

3) The great differences in the length of the awns is due in particular to combinations of the two factors A and E.

409 — “Reggiano Maize”, A New Variety of Early Dwarf Maize Obtained in Italy by Hybridisation and Selection. — SUCCH, A., in *Le Stazioni sperimentali agrarie italiane*, Vol. I, Pt. 9-10, pp. 401-432. Modena, 1917.

By continual hybridisation and selection work the author has succeeded in fixing and propagating a new type of early dwarf maize, called “reggiano maize”, which is much earlier and a better cropper than that used as original material. This original variety, obtained from seed imported from America, has been cultivated since 1894 in the province of Bologna, and since 1897 in that of Reggio-Emilia, the only selection being that of the best ears.

The author describes experiments carried out by him at the experimental fields of the School of Agriculture of Reggio-Emilia, taking into consideration the following characteristics: —

Yield, earliness, length of culm, height of insertion of the ear above the ground, total number of internodes, number of internodes below the ear, length of ear and of peduncle, number of rows of seed per ear.

Of the ears selected since 1912 from the early-flowering plants, numbers 3 and 7 gave the best results, owing to the stability of their characters. In the present hybridisation experiments possible reversion to unknown types which took part in the preceding natural crosses is avoided.

*Data obtained in 1914: averages of 10 culms.*

	Crossings made in 1914	
	3 ♀ × 7 ♂	7 ♀ × 3 ♂
Length of culm, in centimetres. . . . .	0.83	0.81
Height of insertion of ear, in centimetres. . . . .	0.23	0.28
Total number of internodes . . . . .	7.22	7.12
Number of internodes below the ear . . . . .	3.55	3.60
Length of ear, in centimetres . . . . .	17.33	16.37
Length of peduncle, in centimetres . . . . .	9.44	13.40
Number of rows of grain per ear. . . . .	14.70	15.25

The characters are not constant only in the products of the reciprocal crossings 3 ♀ × 7 ♂ and 7 ♀ × 3 ♂, but also in plants resulting from self-fertilisation, so that, by a suitable fusion of the characters of the parent plants, another type — “reggiano-maize” — stable, homogenous, and really superior, tends to separate out.

Below is a summary of the methods adopted by the author to intensify still more the selection of this new type starting from the reciprocal crossings 3 ♀ × 7 ♂ and 7 ♀ × 3 ♂:

A. — SOWING. — 1) Isolate the experimental fields with protective belts so as to prevent cross-fertilisation, using, to form these belts, giant Caragua white maize, which usually flowers a month later than early dwarf maize.

2) Sow on one line only the seed from each ear.

B. — DURING GROWTH. — 3) Suppress sterile plants before the opening of the anthers.

4) Castrate the male flowers, not only of all the plants to be used for hybridisation, but also of all weak plants, or those higher or later than usual.

5) At the time of flowering mark the best plants, choosing those which are earliest and strongest.

C. — AT HARVEST AND FOR THE HARVESTED CROP. — 6) At the time of harvest choose the earliest, strongest plants, most rich in ears, normal and without disease (about 5 feet long, with 8 internodes).

7) Choose the ears:—*a*) inserted the lowest, *i. e.* at 9.82 to 11 inches from the ground at the 4th. node; *b*) with a peduncle about 6 inches long; *c*) the thickest.

8) Keep the ears enclosed in their sheath for a few days.

9) Remove the sheath and choose the ears which:—*a*) are thickest; *b*) are most typical; *c*) are fullest, with well-plumped grain at the top; *d*) have the most regular rows; *e*) have the most numerous rows; *f*) show the best characters as regards number, size, colour and fullness of grain.

10) Choose the grains on the ears, discarding: — *a*) those of the tip and the base; *b*) the most irregular; *c*) the more or less aborted, often found between normal grains or those above the normal.

The new type obtained by these methods from seed imported directly

from America belongs to the species *A Zea Mays* Bonaf., Class I : early maize, group *a* : yellow maize. Its characteristics are : —

- 1) Long culm, averaging 3.28 to 3.60 feet, between the first non-rooted node, on the level of the ground and the joint node of the peduncle of the male inflorescence. Total length of the plant about 4.92 ft.
- 2) Number of internodes : — 8 to 9.
- 3) Number of leaves : — 9 to 10, with strong and well developed blade, sheath thick, causing a marked thickening at the level of the nodes.
- 4) Ear normal, joined at the 3rd. or 4th. node, at 9.82 to 11 inches above the ground, with peduncle about 3.93 to 5.90 inches long ; bare ear, about 6.68 to 6.86 inches long, slightly conical, rounded at the tip.
- 5) Grain a fine, bright yellow, arranged in 16 to 18 rows, weighing, on an average 40 gm. per hundred.
- 6) Rachis, firm.
- 7) Yield, slightly inferior to that of "Agostano" maize (63  $\frac{1}{2}$  cwt. per acre as compared with 66 cwt. for the latter, according to BENDANDI of the Modena Agricultural Station).

8) In the normal climate of the province of Reggio-Emilia, the new type, sown at the beginning of May, flowers in the second half of June, and ripens at the end of August.

Cultural tests made in 1912 to compare the new selected type with the original variety (seed from Bologna) confirmed the marked superiority of the new one as regards shortness and earliness ; its height is only 5 feet as compared with 6  $\frac{1}{2}$  for the other, and it ripens 15 days earlier.

410 — **The Improvement of Cotton by Selection, in India.** — *Bulletin of the Imperial Institute*, Vol. XV, No. 2, pp. 149-177. London, April-June, 1917.

Selection experiments with cotton have been carried out for several years in many of the Agricultural Stations in India, and are still being continued with important results.

**CENTRAL PROVINCES AND BERAR.** — Selection is carried out at the Sindewahi (Chanda District, Central Provinces) and Akola (Berar) Agricultural Stations. The following cottons are grown :

An American upland cotton called "buri".

The native cotton "bani" (*Gossypium indicum*).

The native cottons, "Jari", which include a mixture of races of *Gossypium neglectum* namely, *rosea*, *cutchica*, *malvensis* and *vera*.

A selected line known as k 7.

A number of hybrids, amongst them bani  $\times$  *rosea*, bani  $\times$  mathio, bani  $\times$  deshi Lahore (this last is a white-flowered variety introduced from the Punjab).

Of all the cottons studied, *rosea* gives the best yield, and is now grown over 700 000 out of the 4 750 000 acres under cotton in the Central Provinces. In 1914-15 it gave a profit exceeding that given by ordinary cotton by 21s. per acre. The yields of lint obtained from the several varieties at Akola in 1916 were :

Variety	Lbs. of lint per acre
<i>Gossypium neglectum rosea</i> . . . . .	267.5
» » <i>culchilla</i> . . . . .	255.9
» » <i>malvensis</i> . . . . .	190.4
» » <i>vera</i> . . . . .	171.0
Saugor jari . . . . .	247.6
Berar jari . . . . .	172.4
Buri . . . . .	180.1
Bani . . . . .	148.8
Bani × deshi Lahore (Sindewahi cross) . . . . .	184.5

PUNJAB. — The experiments are being carried out at Lyallpur with American, Egyptian, and Cambodia cottons, but only the American varieties have given positive results, and many pure lines have been isolated from the varieties acclimatised at Lyallpur. Of these 4F is distinguished by the quality and yield of its lint and by its resistance to insect pests. In 1914-15 2 000 acres were sown with this variety, and it is hoped that in time it will replace entirely the ordinary American cotton of the district.

The native cotton of the Punjab, known as "desi", consists of a mixture of varieties of the three species *Gossypium sanguineum*, *G. indicum* and *G. neglectum*. Several main types have been isolated by selection, but they are all inferior to American cotton. Mention may be made of a form of *G. sanguineum*, which gives good yields, and is grown over 1 450 acres in the Lyallpur district.

BOMBAY. — Selection, carried out at the Mirpurkhas Farm, Sind, deals particularly with the Mitafifi (Egyptian), Sindhi (indigenous) types and several improved American Upland cottons with very long lint.

All the samples examined at the Imperial Institute in 1912-13 were of good quality. In a few cases only (Toole's, Griffen, and Black Rattler) was there a little irregularity in length or strength, but these defects might be removed by acclimatation and systematic selection of seed from the best plants.

BURMA. — The native cottons of Burma are, on the whole, of poor quality, but some of the strains have a fairly long staple, and are equal in value to the best Indian cottons, and only a little inferior to "middling" American. The most widely cultivated variety in the dry, central tracts of Burma, is "wa-galé", or "wa-pyu", which supplies  $\frac{3}{4}$  of the total production of the country. Then come "wa-ni", with red fibre, grown on a small scale for local use where "wa-galé" is cultivated, the two being often mixed; "wa-gyi", a perennial cotton with white fibre, grown to a small extent in Myingyan, Thayetmyo and Minbu; "thinbaw-wa", a form of Pernambuco cotton grown in the Amherst district. From the wa-gyi and wa-galé varieties have been isolated lines with specially high ginning yields. Native cotton is inferior to Cambodia cotton obtained from Madras and now being introduced into several districts.

411 - The Effect of Selection on "Kumpta" Cotton and on the Quality of Its Fibre, in India. — See No. 419 of this Review.

412 - Yields of Different Varieties of Maize in Illinois. — BURLISON, W. I. and ALLYN, O. M., in the *University of Illinois Agricultural Experiment Station, Bulletin No. 191*, pp. 409-424, 11 Tables. Urbana, Illinois, August, 1916.

CEREAL  
AND PULSE  
CROPS

The experiments described were carried out during 15 years, chiefly at Dekalb (Dekalb county), Urbana (Champaign county), and Fairfield (Wayne county), Illinois, and are still in progress.

The climatic conditions in the different parts of Illinois vary greatly. The rainfall in the north is 33.64 inches per annum, in the centre, 35.76 inches, and in the south, 40.25 inches. The average length of the growing season is 166 days in the north, 173 days in the centre and 188 days in the south. The soil in which the experiments are carried out is brown silt loam at Dekalb and Urbana, and grey silt loam on compact clay at Fairfield. The fields have, for the most part, been regularly supplied with phosphate rock, limestone, and either farm manure or crop residues. The methods used are those adopted by the leading maize growers.

NORTHERN ILLINOIS. — The experiments were started in 1903 at Myrtle (Ogle county), transferred in 1905 to Sycamore (Dekalb county), and, since 1906, continued at Dekalb. The rotation at Dekalb was maize, maize, oats and clover. The varieties tested were: — Riley's Favourite, Reid's Yellow Dent, Funk's 90 Day, Leaming, Goldmine, Pride of the North, Boone County White, White Superior, Western Plowman, Champion White Pearl, Silvermine, Golden Eagle, Farmer's Interest and Lockwood's Yellow Dent. Western Plowman invariably gave the highest yield with the exception of Will County Favourite, grown for two years only, and the same variety by origin. The other high-yielding varieties grown for a minimum of four years are in order of yield, Riley's Favourite, Griffith's Early Dent, Reid's Yellow Dent, Hecker's Red and Funk's 90 Day.

CENTRAL ILLINOIS. — The trials reported from Urbana have been in progress since 1901. The rotations were: — 1) maize, maize, oats and clover; 2) wheat, maize, oats and clover; 3) combination rotation of alfalfa, maize potatoes and soybeans. Of the 17 varieties tested, Reids' Yellow Dent gave the highest yield of any grown for a minimum of five years. Very good yields were obtained with Boone County White, Champion White Pearl, Leaming, Silvermine and Riley's Favourite, while Golden Eagle, Farmer's Interest, Johnson County White and Beatty's Yellow proved highly satisfactory.

Fifteen varieties were also tested at Decatur, Auburn, Mattoon and Sibley. In these trials Reid's Yellow Dent was out-yielded by three varieties. — Funk's Yellow Dent, Farmer's Interest and White Superior — but the difference was not marked, and the varieties only tested for two years.

SOUTHERN ILLINOIS. — The tests were started in 1906. The highest yields for a minimum of four years were obtained with the following varieties in the order given: — Funk's 90 Day, Reid's Yellow Dent, Perrine's White Pearl and Chinese Poor Land. Sutton's Favourite, Strout's Red,

Will County Favourite and Western Plowman, though grown for one year only, promise well.

Experiments were also made on untreated land at Fairfield. They gave the expected results; *i. e.* varieties grown commonly in southern Illinois adapted to the soil out-yielded those which gave the best results under less unfavourable conditions. In these trials Champion White Pearl, Perine's White Pearl and Easterly's White varieties gave the highest yields for the three years 1911-1913.

The bulletin concludes with a brief history of certain varieties of maize.

413 - **A New Early Variety of Dwarf Maize, Obtained in the Province of Reggio-Emilia, Italy.** — See No. 409 of this *Review*.

414 - **Indo-Chinese Rice.** — CAPUS, G., in *Annales de Géographie*, Year XXVII, No. 145, pp. 25-42. Paris, January 15, 1918.

The methods of increasing the production of rice in Indo-China and of improving its quality are discussed. The different varieties grown ("Gocong" or "Kadong", "Baixan" and "Vinhlong" or "Longho") should be sorted, both for milling and for exportation. The selection of seed is prevented by the hold of the Chinese over the rice trade. The Chinese buy the rice in small lots, which they mix for sale. The only method of opposing this practice would be by founding European factories which would insist on sorting when buying.

At the exhibition organised in 1911 by the Colonial Institute of Marseilles were 796 samples of rice from Cochinchina, together with information on their origin, yield per acre and weight of grain per bushel. An investigation into the commercial value of the hulled rice showed that, besides very many valuable varieties, 14 at least, qualified as very valuable, were particularly mentioned because of their commercial qualities. The value of the white rice of 19 varieties was stated to be equal to those quoted at 10s. to 15s. per cwt.

Special stress is laid on:— 1) the usefulness of improving the quality and yield by the choice of seeds from the best native varieties (a method superior to the introduction of good foreign varieties, for this is often difficult and the introduced varieties degenerate rapidly); 2) individual selection; 3) the use of pure and pedigreed lines; 4) the improvement of the crops.

Cochinchina produces annually over 2 million metric tons of paddy on 3 706 650 acres of rice fields. If an increase of 20 % of the present yield were obtained, the annual gain would be 400 000 metric tons, representing a value of about £ 158 590. The annual production of about 5 million metric tons of the three rice-growing countries of the Union (Cochinchina, Cambodia and Tonkin) would increase by about 1 million tons, worth, at the normal local price of paddy, £ 396 500.

#### STARCH CROPS

415 - **The Composition of the Potato Plant at Various Stages of Development.** — RAMSAY, J. T. and ROBERTSON, W. C., in *The Journal of the Department of Agriculture of Victoria*, Vol. XV, Pt. 2, pp. 641-655 + 2 figs. Melbourne, November, 1917.

*Object of the experiment.* — This experiment was carried out to determine:— 1) the rate of assimilation of food from the soil; 2) the relative

proportion of each of the principal elements contained in the plant at various stages of its growth.

*Method.* — The crop was grown in synthetic soil composed of 13 parts Carrum sand, 2 parts clayloam surface soil and 1 part well-rotted farmyard manure. When well mixed its composition per 100 000 parts was, nitrogen 103, phosphoric acid 22, potash 82, lime 201, magnesia 55. It was put in small 18 × 18 × 18 inch hardwood boxes, each of which held 130 lbs. of soil. The potatoes were planted 4 inches below the surface, and the boxes placed in the ground, their top being practically level with the surface. Care was taken to ensure good draining and the plants were well watered. Each box received as fertiliser: — superphosphate  $\frac{1}{2}$  oz., ammonium sulphate 1 oz., dried blood 1 oz., potassium sulphate  $\frac{1}{2}$  oz. The potatoes were planted on December 17, 1916. All the potatoes were of the Up-to-Date variety and their average weight was 75 grams. When the plants emerged a top dressing of  $\frac{3}{4}$  oz. of sodium nitrate per box was applied. Later each box was mulched with buffalo grass (*Buchloe dactyloides*) cuttings, and the surface soil was kept loose throughout the period of growth.

*Harvests.* — The harvests were at intervals of approximately one month (see Table I). The total period of ripening was 124 days. Care was always taken to collect the whole plant without damaging or tearing the root.

*Results.* — The results were remarkably uniform in the duplicate sets from each harvest, they are summarised in the following tables.

#### TOTAL DRY MATTER IN THE PLANT.

TABLE I. — *Yield of dry matter at various stages of growth.*

Date of harvest	Grams of dry matter per plant				Dry matter per acre (12 000 plants per acre)

n. e. = not estimated.

The results in these tables show distinctly that the potato plant does not develop in a uniform manner throughout the period of its growth. The development of the root practically ceases at the end of the second month when 93% of the root are already formed. The development of the haulms ceases after the 3rd. month; only the tubers continue to grow during the 4th. month. During the 1st. month the plant produces 9% of its total dry matter, 50% during the 2nd., and 91% during the 3rd. Thus the life of the potato really includes three cycles—preparation (it is here the plant needs assistance), production, maturation.

The results obtained by the authors agree with those obtained by H. WILFARTH and H. ROMER at the Ducal Agricultural Station at Bernberg, Anhalt (Germany), in 1903-1904. These workers carried out experiments on a much larger scale to determine whether, during growth, the potato plant returns part of its food to the soil.

The principal results may be summarised as follows:—

- 1) The 3 essential plant foods—nitrogen, potash and phosphoric

TABLE V. — *Chemical composition of the potato plant at the different harvests (total dry*

Harvest	Composition, per cent.					Yield in lbs. per acre (12 000 plants per acre)

\* Owing to the advanced stage of decomposition difficulty was experienced in collecting all the roots at the 4th. harvest. The loss was about 30 %, which would make the analytical figures obtained from the 4th. harvest of the roots about equal to those obtained from the 3rd.

acid — once absorbed by the potato plant are utilised, no migration from the plant to the soil taking place.

2) The critical period of growth is the first 6 to 8 weeks.

3) The greater part of the phosphoric acid enters the plant at the early stage of growth, concentrating in the haulm, and then playing an important part by migrating to the stolons for tuber formation.

4) Potash and nitrogen play a consistently even part throughout the growing period.

5) Practically the whole of the root development takes place during the first 2 months.

TABLE VII. — *Soluble plant-food in the potato haulm at the different harvests.*

Harvest	Nitrogen		Phosphoric acid		Potash	
	% soluble	of total in plant	% soluble	of total in plant	% soluble	% of total in plant
1st. . . . .	1.55	32	0.81	80	7.13	110 (approx)
2nd. . . . .	0.80	20	0.67	72	5.34	86 ( " )
3rd. . . . .	0.77	30	0.27	75	4.50	100 ( " )
4th. . . . .	0.42	21	0.27	80	3.54	100 ( " )

6) Haulm development is most active during the first 2 months.

7) The amounts of lime and magnesia assimilated by the potato plant seem to bear a definite relation.

8) The very young potato tuber is richer in phosphoric acid than the semi or mature tuber.

9) Phosphoric acid and nitrogen present in the seed set are largely utilised for sprout formation (25 % for the former and 50 % for the latter). Potash, apparently, is not utilised directly.

10) The results of the experiments taken collectively show that the plants must be manured during the first month.

11) Potatoes can be grown on poor sandy soil provided that available plant-food in the form of artificial fertilisers and farmyard manure are judi-

ciously applied. In such cases the quantity and quality of the produce may may be favourably compared with that from the best potato soils.

12) The value of the dried haulms and roots may be compared to farmyard manure in favour of the dried haulms, 1 ton of which supplies 3 times as much nitrogen and phosphoric acid, and about 10 times as much potash as 1 ton of farmyard manure.

13) The composition of the potato tuber under experimental conditions may be influenced in so far as the phosphoric acid content is concerned.

14) During the growing period the potato plant utilises phosphoric acid, nitrogen and potash, in the proportion of 1, 4, 6, *i. e.* 1 part of phosphoric acid to 4 parts of nitrogen to 6 parts of potash.

416 - **Methods of Applying Fertilizer to Sweet Potatoes.** — DURST, C. E., in the *University of Illinois Agricultural Experiment Station, Bulletin* No. 188, pp. 268-278, 2 Figs., 6 Tables Urbana, Ill., April, 1916.

Fertiliser experiments with sweet potatoes were carried out during the five years 1910-1914 at Anna, in Union County, the most important sweet-potato growing centre. Eight plots, each 66 × 20 feet, were used; two of these (plots 1 and 5) were control plots, three (plots 6, 7, and 8) were fertilised under the ridge, and three (plots 2, 3 and 4) were fertilised broadcast, each with:— 1) home mixed fertiliser (2 parts by weight of steamed bone, with 12.5 % phosphorus, 2 parts of dried blood, with 14 % nitrogen, and 1 part potassium sulphate, with 42.5 % potash); 2) 640 lbs. manure, containing 10 lbs. nitrogen, 3 lbs. phosphorus and 8 lbs. potash per ton; 3) 16 lbs. of steamed bone.

The potatoes harvested were graded according to the local method into "table" potatoes (1½ inch or more in diameter, of good shape), "seed" potatoes (of good shape and rather smaller than the first class), and "strings" (deficient in size and shape). The average yields obtained were:—

Plot	Table potatoes, bushels per acre.	Seed potatoes, bushels per acre.	Strings % in weight of table potatoes
1	76.07	35.17	24.29
2	94.16	33.32	20.93
3	106.42	33.82	20.74
4	89.57	33.51	20.57
5	80.96	30.03	26.57
6	103.28	29.12	25.41
7	130.92	28.15	19.26
8	100.79	33.38	20.76

As the price of sweet potatoes varies according to the season in which they are marketed the results given have been based on two set prices:— 1) 50 cents per bushel for the table grade and 25 cents per bushel for the seed grade; 2) 75 cents per bushel for both grades (price of stored potatoes).

All the fertilised plots gave higher unit yields than the control plots, but only manure and steamed bone under the ridge gave a sufficiently great increase to bring in any appreciable profit when the cost of the fertiliser

and the elements left in the soil are taken into account. All the treatments supplied more of the elements for which they were used than was removed by the crop. Manure applied under the ridge not only gave the highest net returns, but also left more fertiliser value in the soil than any of the other treatments except manure broadcast. Manure also leaves considerably more organic matter in the soil than does any other fertiliser.

**Conclusions.** — All the fertiliser treatments tested in the experiments increase both the unit yields and the percentage of table potatoes. With the possible exception of the home-mixed fertiliser, higher percentages of table potatoes are produced when the fertiliser is applied under the ridge than when it is broadcast. When considering the advisability of any of these treatments, the prices likely to be received for the crop should be taken into account, as the higher these are, the greater is the profit made on the fertiliser.

A large proportion of the fertiliser remains in the soil for the next crop.

FORAGE CROPS,  
MEADOWS  
AND PASTURES

417 — **Grasses and Other Fodder Plants of Victoria, Australia.** — AUDAS, J. W., in *The Journal of the Department of Agriculture of Victoria*, Vol. XV, Pt. 12, pp. 711-723, 3 Tables, 3 Figs. Melbourne, December, 1917.

**NATIVE FODDER GRASSES.** — The native grasses of Victoria belong to 136 species, divided among the following 49 genera : —

*Panicum*, 15 species; *Chamaeraphis*, 2; *Isachne*, 1; *Oplismenus*, 1; *Setaria*, 4; *Spinifex*, 2; *Tragus*, 1; *Neurachne*, 3; *Zoysia*, 1; *Imperata*, 1; *Pollinia*, 1; *Lepturus*, 2; *Hemarthria*, 1; *Andropogon*, 8; *Chrysopogon*, 2; *Sorghum*, 2; *Anthistiria*, 2; *Alopecurus*, 1; *Tetrarrhena*, 3; *Microlaena*, 1; *Hierochloa*, 2; *Aristida*, 6; *Stipa*, 13; *Dichelachne*, 2; *Pentapogon*, 1; *Amphipogon*, 1; *Pappophorum*, 1; *Sporobolus*, 3; *Agrostis*, 3; *Deyeuxia*, 7; *Deschampsia*, 1; *Trisetum*, 1; *Anisopogon*, 1; *Danthonia*, 6; *Cynodon*, 1; *Chloris*, 2; *Eleusine*, 1; *Poa*, 4; *Glyceria*, 5; *Diplachne*, 2; *Triodia*, 1; *Distichlis*, 1; *Bromus*, 1; *Eragrostis*, 7; *Elythrophorus*, 1; *Triraphis*, 1; *Agropyron*, 3; *Arundo*, 1.

All are fairly well distributed throughout the state. The most valuable and nutritious grasses amongst them are 15 species of *Panicum*, 8 of *Andropogon*, 7 of *Deyeuxia*, 7 of *Eragrostis* (some of which are remarkable for their resistance to drought), 4 of *Glyceria*, 2 of *Anthistiria*, 2 of *Chloris*, 2 of *Diplachne*, 4 of *Poa* (one of which might be used for the manufacture of fibre), 3 of *Sporobolus* (one of which could be used in paper-making).

On the other hand, there are a large number of undesirable grasses, covering, in some places, a wide area, depreciating its stock-carrying capacity. They are : —

*Stipa elegantissima*; *S. flavescens*; *S. teretifolia*; *S. eremophila*; *S. setacea*; *S. Luehmanni*; *S. acroclita*; *S. McAlpinei*; *S. Muelleri*; *S. semibarbata*; *S. pubescens*; *S. aristiglumis*; *S. scabra*; *Aristida arenaria*; *A. Behriana*; *A. leptopoda*; *A. vagans*; *A. ramosa*; *A. calycina*; *Triodia irritans*, th's last chiefly on account of its sharp-pointed leaves.

**NATIVE PASTURE GRASSES : —**

*Andropogon pertusus*, pitted grass; *A. affinis*, crown beard grass; *A. refractus*, turpentine grass; *A. sericeus*, silky blue grass; *Agropyron scabrum*, common wheat grass; *Anthistiria imberbis*, kangaroo grass; *Chloris truncata*, windmill grass; *C. acicularis*, lesser star grass; *Cynodon Dactylon*, Indian couch grass; *Danthonia penicillata*, Wallaby grass; *Dichelachne*

*crinita*, long hair plume grass; *Eleusine cruciata*, finger grass; *Eragrostis Brownii*, common love grass; *E. pilosa*, soft love grass; *Microloena stipoides*, weeping grass; *Panicum decompositum*, umbrella grass; *P. divaricatissimum*, spider grass; *P. effusum*, hairy panic grass; *P. gracile*, slender panic grass; *P. leucophacum*, cottony panic grass; *P. Mitchellii*, spreading panic grass.

#### NATIVE GRASSES FOR MOIST SOILS: —

*Glyceria fluitans*, manna grass; *G. Fordeana*, sweet swamp grass; *G. ramigera*, bamboo grass; *Hemarthria compressa*, mat grass; *Imperata arundinacea*, blady grass; *Panicum melantherum*, black seeded panic grass; *Arundo Phragmites*, common reed grass; *Microloena stipoides*, weeping grass; *Isachne australis*, swamp millet; *Diplachne fusca*, brown beetle grass; *Danthonia nervosa*, swamp Wallaby grass.

#### NATIVE GRASSES FOR DRY SOILS: —

*Amphipogon strictus*, bearded heads; *Anisopogon avenaceus*, oat spear grass; *Echinopogon ovatus*, hedge hog grass; *Eragrostis lacunaria*, Mullee love grass; *Neurachne Mitchelliana*, Mitchell mulga grass; *Pappophorum nigricans*, nigger head; *Pollinia fulva*, browntop; *Chloris truncata*, windmill grass; *Eleusine cruciata*, finger grass; *Panicum effusum*, hairy panic grass; *P. prolutum*, pallid panic grass; *P. decompositum*, umbrella grass.

#### NATIVE GRASSES FOR BINDING SANDS: —

*Distichlis maritima*, salt grass; *Imperata arundinacea*; *Festuca littoralis*, coast fescue; *Spinifex hirsutus*, hairy spinifex; *Sporobolus virginicus*, Virginian rat-tail grass; *Zoysia pungens*, prickly couch grass; *Hemarthria compressa*; *Cynodon Dactylon*.

During spring and summer there is generally abundant, rich pasture, but the want of it is usually felt in winter. One of the most common grasses is *Danthonia penicillata*; it is very nutritious and relished by all kinds of stock. *Anthistiria imberbis* produces little seed, and it is advisable to remove stock from it during spring and summer; if this is done it grows sufficiently high to hide sheep, which like it very much. Stock willingly eat *Imperata arundinacea*, which is also used for thatching. *Panicum Crus-Galli* attains a height of 4 to 5 feet, and is most suitable for moist districts. Perennial are *Pappophorum nigricans*; *Eragrostis Brownii*; *Amphipogon strictus*; *Panicum divaricatissimum* (drought-resistant); *P. gracile*; *Microloena stipoides*; *Hemarthria compressa*; *Festuca littoralis*; *F. duriuscula* (composition of grass dried at 212° F: — soluble albuminoids, 0.44 %; insoluble albuminoids, 3.94 %; digestible fibre, 17.18 %; woody fibre, 60.99 %; soluble mineral matter, 4.01 %; insoluble mineral matter, 2.26 %; chlorophyll, soluble carbohydrates, etc., 11.18 %; the grass contains 61.98 % of water).
